RELOADING HANDBOOK

- FOR RIFLE, PISTOL, SHOTSHELL AND MUZZLE LOADING
- NEW, ENLARGED LOADING DATA SECTION
- NEW, UP-TO-DATE REFERENCE SECTION

PRESSURE POWDERS
PRIMERS BULLETS
CASES ACCURACY

44th EDITION

How to use your NEW Lyman HANDBOOK

From cover to cover, your 44th edition of the Lyman Handbook is ALL NEW. Almost double the size of any previous edition, it is completely different, and far more thorough in its coverage of the latest reloading procedures and data. We believe you will find it the most authoritative handbook available — and the easiest to use and comprehend.

For quick location of subject matter, each section is color coded and finger tabbed (see right). The new Reference section contains information on pressures, powders, primers, etc., all important for a sound knowledge of reloading. Data sections have been enlarged and all data has been retested to insure its accuracy. At the beginning of each Data section, a preamble explains how the data should be used.

We labored long and hard to make this 44th edition the true "bible" of reloading. While we believe we accomplished this, we hasten to acknowledge the valuable assistance which we received from many able people from the following firms, and for the use of their products in our research: Du Pont Powder Co., Hercules Powder Co., Remington Arms Co., Winchester-Western, Marlin Firearms Co., Weatherby, Inc., Savage Arms, O. F. Mossberg & Sons Inc., Smith & Wesson, Colt Firearms, Ed Agramonte Gun Collection, International Guns, Inc., Norma-Precision, Sierra Bullets, Inc., Alcan, Inc.

RIFLE

Blue section covers rifle cartridge reloading and rifle data.

PISTOL

Green section covers pistol cartridge reloading and pistol data.

SHOTSHELLS

Yellow section covers shotshell reloading and data, plus additional information pertinent to shotshell reloading.

MUZZLE LOADING

Black section covers the loading, use and care of modern "replica" firearms.

REFERENCE

White section should be read in conjunction with all other sections.

RELOADING PISTOL CARTRIDGES

PISTOL DATA

Lyman

since 1878

The late William Lyman founded the Lyman Gun Sight Corporation in 1878 . . . nearly a century ago. In the beginning, the company's only product was the then revolutionary tang sight for rifles. As the business grew and prospered over the years, "Uncle" Will Lyman added many new products to the line, personally guaranteeing the quality of each one as it came along, and always maintaining a sincere concern for customer service and satisfaction. To him, his customers were his friends.

Today, there are several hundred products listed in the Lyman catalog: A complete line of Metallic and Telescopic Sights; Shotgun Chokes; Reloading and bullet casting equipment. Although Will Lyman's original product, the tang sight, is no longer being made, his insistence on quality and service has become an honored tradition . . . . . carried on through three generations of the Lyman family.

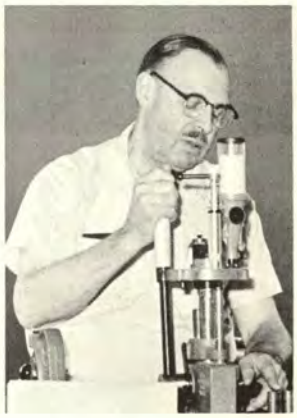
Over 40 Years of Reloading . . .

Lyman has over forty years experience in reloading dating back to 1925 when the Ideal Reloading Tool Company was purchased from John Barlow. Your present 44th Reloading Handbook is actually a continuation of Mr. Barlow's original Ideal Handbook which was the first reloading guide published in this country.

LYMAN Technical Staff

Ed Matunas

Charlie Norton



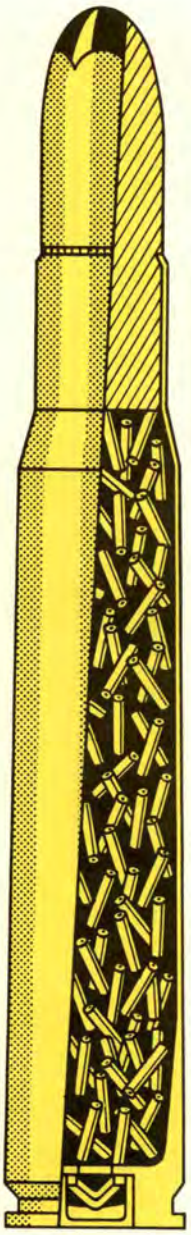
Lysle Kilbourn

Times have changed since Will Lyman answered each day's correspondence. The three people who comprise the Lyman technical staff . . . . . Ed Matunas, Charlie "Red" Norton and Lysle Kilbourn . . . . . now handle a daily bombardment of technical mail. These men competently carry on the tradition of friendly personal service to our customers. They analyze and offer solutions to reloading problems for shooters the world over. If you have a reloading problem with which you need assistance, feel free to write to one of these men.

Blue Trail Range

The Lyman family interest in shooting extends beyond the business profit motive. Connecticut is distinctive in having the Blue Trail Rifle Range — built by the Lyman Gun Sight Corporation. Located in Wallingford, an easy two hour drive from New York, or Boston, the Blue Trail Rifle Range serves all of Southern New England and New York for individual practice and tournament competitions.

Why Reload Cartridges?



Here's a factory 30/06 It will cost you 25¢

You can reload the same shell for only 8¢ . . . . . but that's not the whole story . . .

Economy, of course, is an important reason for reloading. A savings of 17 cents on every round reloaded is not to be sneezed at. However, there are further rewards for the do-it-yourself reloader. In fact, most reloaders don't pocket the 17 cents. Instead they reinvest it in additional reloading for more pleasurable, more skillful, more knowledgeable shooting.

Reloading ties in naturally with the sport of shooting and makes it more fun. Reloading is a fascinating hobby which widens the scope of the sport for you. For example, by varying the loads in your cartridges, you can use your deer rifle on a greater variety of game. This gives you more opportunities to hunt throughout the year, and it supplies you with plenty of inexpensive ammunition to boot. The man who fires on targets and varmints all summer is apt to have a sharp eye come deer season. So increased shooting versatility is another advantage enjoyed by reloaders.

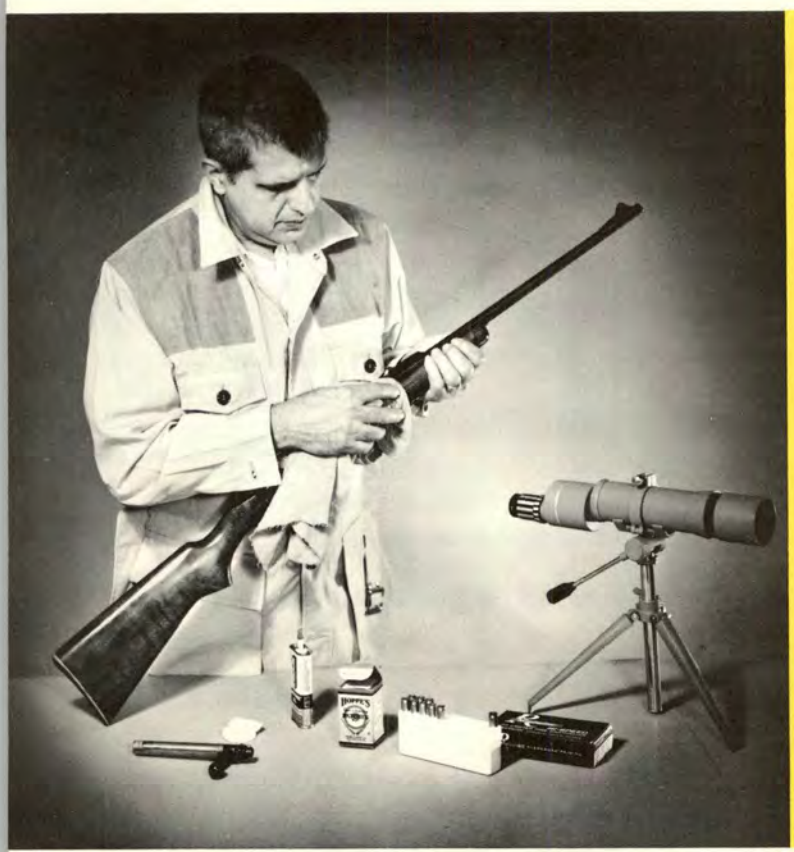
Many men reload for the sheer joy of it . . . for the pride of accomplishment it gives them. Just a few well learned basics of reloading procedures can start you off. It provides sport for every shooting enthusiast: from the casual hunter to the serious bench rest shooter. This is a hobby which you can keep simple, or you can pursue it with all the seriousness of a ballistics engineer. You can start by making good ammo for your trusty old thirty-thirty and stop there. Or, you can go on and on — 'til you rank with the professionals. The choice is yours, and it's fun all the way!

P.S. Many shooters would reload, even if it cost MORE.

HOW SAFE . . . . . HOW EASY is Reloading?

Is reloading safe? Difficult? Can I do it? These are questions that every novice asks.

Men who are now accomplished reloaders may have forgotten their first fumbling attempts at reloading their shells. They were uncertain when they began, as you may be now. Until you have actually reloaded and fired your first cartridge, it is difficult to appreciate how amazingly simple it is. Reloading requires no genius — just mature thinking and common sense. And these are simply the same qualities that are necessary for safe gun handling. Therefore, any qualified shooter can easily and safely reload his own cartridges.



Any qualified shooter can reload his own cartridges.

The novice reloader may have a natural fear of gun powder. He is concerned with the possible dangers of handling and loading the modern smokeless powders. So let's take a look at these powders and find out whether or not such fears are justified.

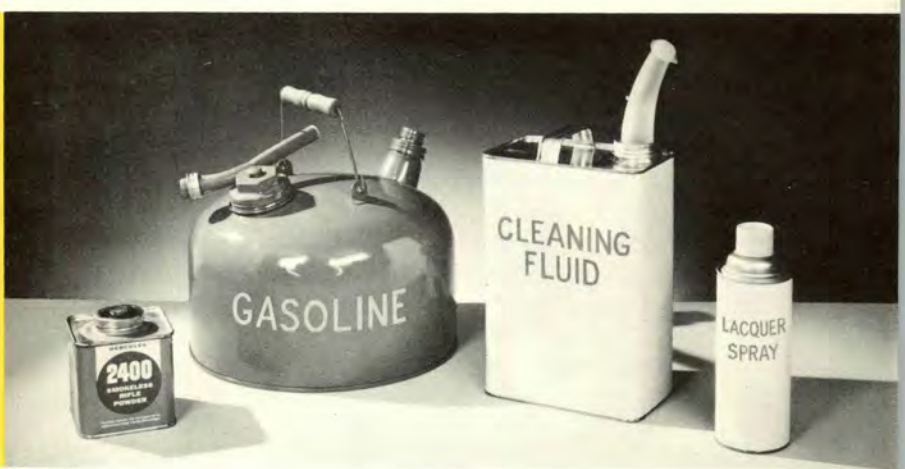
First, you select a powder and charge which are suitable for your caliber and purpose. This information is clearly listed in the Data Section of this Handbook. Once you have as-

certained the correct powder for your requirements, you will have no difficulty in identifying it in your dealer's store. All commercially available powders are sold in factory sealed containers with the identifying name or number clearly printed on the label. This is your assurance that you are purchasing the exact powder that you specify. The sealed can is your assurance that the contents have not been tampered with.

The reloader purchases powder in factory sealed and clearly labeled canisters.

Reloading powders are classified as propellants, not explosives. These powders when properly used, will burn when ignited, but they will not explode. Many ordinary liquids with which you are familiar, such as: gasoline, benzine, naphtha, lacquer, and some paints, require far more careful handling than do the modern smokeless powders. Combustible fumes released by the liquids are quite easily ignited. Powders, however, require direct and positive ignition. All that is required for complete safety is, reasonable care, such as not smoking when loading.

Of these four items, the can of rifle powder is the safest to handle and store.



As modern powders are easily identified and safe to handle, the only other concern to the reloader is to determine accurately the proper charge. Here you depend on the accuracy of your powder scale. Today's reloading scales, such as the Lyman-Ohaus D-5, are designed specifically for the weighing of powders. They are guaranteed accurate to one-tenth of a grain which is more than adequate for your most demanding reloading requirement.

Modern powder scales are highly accurate. The Lyman-Ohaus scale shown here is guaranteed accurate to one-tenth of a grain.

The actual mechanics of reloading are fully explained in the "How To Reload" chapter. They consist of six basic procedures which, as you will find upon reading the chapter, are easily understood and simple to learn. If you will follow these reloading instructions, you will quickly grasp the fundamentals of this interesting hobby, and YOU CAN START RIGHT IN MAKING YOUR OWN CARTRIDGES.

After a little reloading experience, your interest and confidence in this rewarding sport will probably increase, and you'll want to become more expert. You'll want to try varying the loads for your rifle . . . experiment for optimum shooting accuracy . . . explore various reloading theories and techniques . . . savor all the pleasures enjoyed by the oldtimers. If so, we have provided you with your "homework" in the reference section of the Handbook. By studying it you will soon acquire a sound knowledge of the subject.

One last thought. Do not be scared off by any technical jargon you encounter. Every sport has its own language and reloading is no different. You'll be talking the lingo in no time. If you should run into an unfamiliar word, check the glossary section in back of Handbook.

Reloading Rifle Cartridges

This chapter is devoted to the basic mechanics of reloading a rifle cartridge. We urge the beginner to read it carefully and to also read the preamble to his data section before attempting to reload. The preamble, located at the beginning of each data section is intended to help you interpret the data and insure its correct use.

CHOOSING YOUR TOOLS

Like most hobbyists, the average reloader eventually accumulates an assortment of tools and accessories which make reloading easier, faster and more professional. The addition of new items to his reloading bench give him a pride of ownership equaled only by the photography bug and the home craftsman. All the beginner needs, however, are a few basic tools. But he should make sure that the tools are of good quality so that they will last him in future reloading activities.

For the instructional text and illustrations in this section, we have selected the tools which we believe are best for the newcomer to rifle cartridge reloading. These few basic tools are easy to operate. They will last for a lifetime of reloading, and they will always be useful regardless of how advanced your hobby may become.

C-FRAME RELOADING PRESS
A strong reloading press is required to supply the necessary leverage. Pictured is the Lyman Spartan*.

RAM, SHELL HOLDER & PRIMING ARM
These items are required to complete your press. Items shown are Lyman Spartan*.

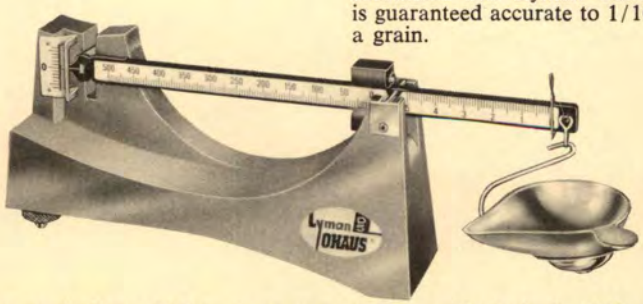
POWDER FUNNEL

CHAMFERING REAMER

SIZING LUBRICANT

RELOADING DIE SET
Quality reloading dies are a must. The set shown here is Lyman All-American*.

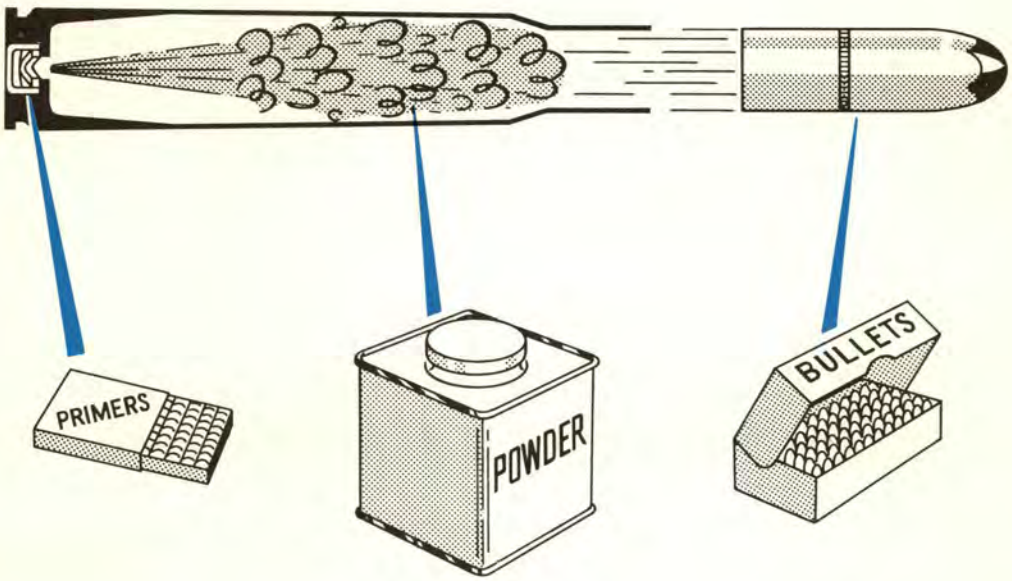
POWDER SCALE
A reliable and accurate scale is required for both safety and performance. The Lyman Ohaus D5 is guaranteed accurate to 1/10th of a grain.



*For retail prices of these items, see catalog section in back of Handbook.

BUYING THE PROPER COMPONENTS

When you fire a bullet, three components, or parts, of the original cartridge are used up. They are: (1) THE PRIMER, (2) THE POWDER CHARGE, (3) THE BULLET.



Before you can reload this cartridge and fire it again, you must purchase new components to replace those which were spent in firing. To select the proper components for your cartridge, turn to the Data Page in this Handbook which lists your cartridge. Make a note of the size of your primer and the diameter of your bullet. These sizes will be required later when you purchase components. At this time you must also choose a bullet weight and decide as to the type of powder that you want to use. At the beginning, we recommend that you select a jacketed bullet of a weight with which you are familiar, and that you begin by loading the "starting load" shown for this bullet weight. Note: Do not use pointed bullets in tubular magazine rifles.

The reference section of this Handbook contains detailed information on primers, powder and bullets. We recommend that the novice read these chapters at his earliest convenience.

GATHERING AND PREPARING CASES

You can always recognize a reloader by his almost fanatical quest for spent cartridges. He not only pockets each round that he fires, but he develops the habits of a pack rat in his zeal to con extra brass from his shooting associates. There is no mystery in his strange behavior. He simply has learned that cartridge brass is valuable, that he can turn it into extra shooting pleasure and save many dollars besides.

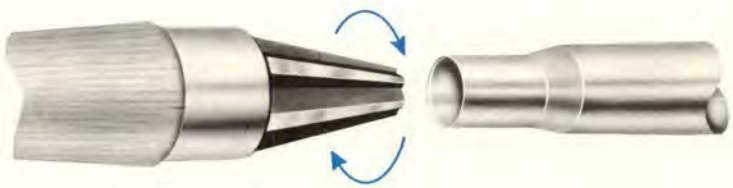
Regardless of the source from which you obtain your first cartridge cases, it is wise to separate them into lots and to keep a record of their history. For example, if you purchase two boxes of loaded factory cartridges on a certain date, keep all forty rounds together and load them as one lot. Maintaining a record of the date of purchase and the number of times you loaded these cases will be helpful in determining your CASE LIFE, and you will benefit later when *TRIMMING is required.

*Trimming is necessary when your cases have lengthened after numerous firings. The trimming of cases is not covered here in the beginner section. See reference section on CASES for complete information.

Before each reloading check your cases for splits, or cracks about the necks and body. These cracks are indications of deteriorated brass probably due to excessive reloading. Reject all cases which show signs of defects, but before you discard them, flatten them with a pair of pliers to prevent their being used again.

Cracks around the neck and splits in the body are indications of deteriorated brass probably due to excessive reloading.

To ease the insertion of the new bullet, you now remove the sharp inside edges from the case mouth. This operation is called CHAMFERING and the small commercial hand reamer does the job easily and with uniformity. Hold your case in one hand while you lightly turn the reamer in the case mouth with the other hand. Remove very little case material and DO NOT cut a sharp knife edge on the case. This operation is required only after the first firing.

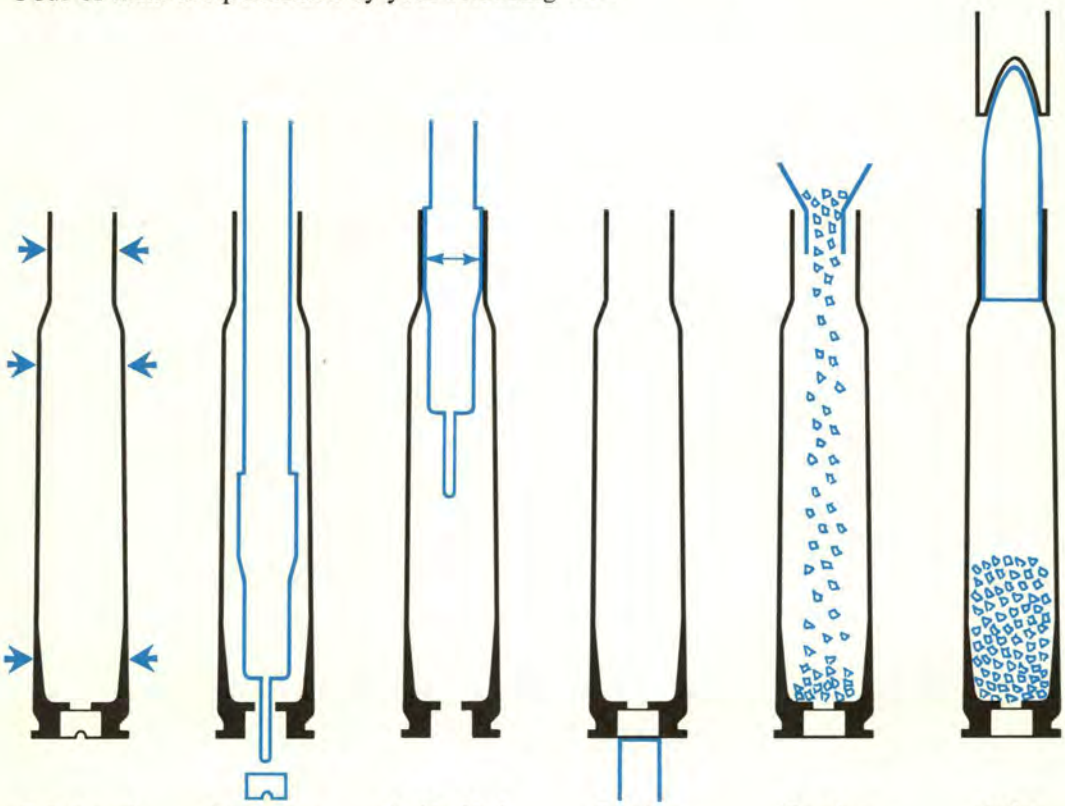


The last operation in preparing your cases for loading is to lubricate them with a suitable lubricant. This prevents the case from sticking in the resizing die and it removes dirt, or grit that might have collected. Wipe your cases carefully with a rag *SPARINGLY greased with Lyman Size-Ezy Lubricant and your cases are ready for loading. After reloading and before firing, always wipe your cases to remove the sizing lubricant.

*Too much lubricant will cause lube dents in the case. Cases dented in this manner may be used for loading as the dents disappear on firing. It is not considered good reloading practice, however, and care should be taken.

MAKING CARTRIDGES

Putting a cartridge together is really a series of SIX very basic mechanical operations. Four of them are performed by your reloading dies.



*Performed by your dies.

Let's first understand why these six operations are necessary to reload a cartridge.

1. FULL LENGTH RESIZING: When a cartridge is fired, the brass walls of the case swell to the chamber size of the rifle. These walls remain pretty much at their expanded size and do not snap back to their original dimensions. Since all rifle chambers are not identical, cases fired in one rifle may not chamber in another unless their walls are compressed to a standard diameter which is acceptable in all rifles. This operation is called resizing.
2. DECAPPING: This operation is simply knocking out the old or fired primer.
3. INSIDE NECK EXPANDING: After the resizing operation, the neck of the case will be too small to accept the bullet. Inside neck expanding enlarges the inside diameter of the neck to a size which will receive the bullet and hold it securely.

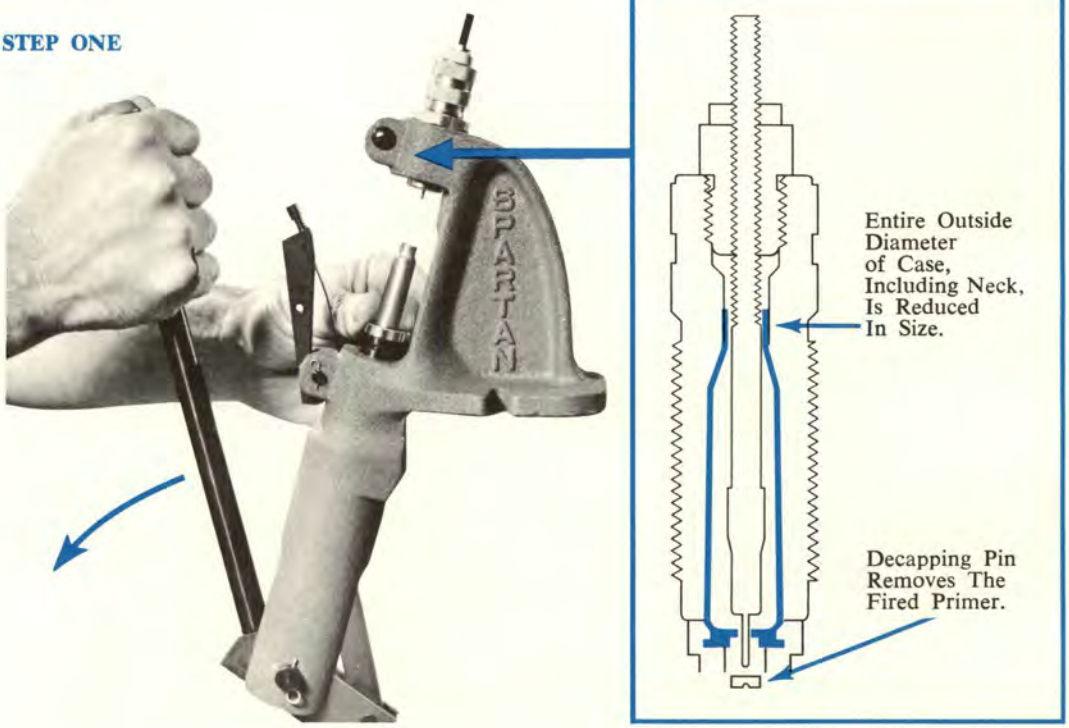
4. PRIMING: This operation is simply inserting a new primer into the case.
5. INSERTING POWDER: This operation is simply weighing out and pouring a suitable charge of powder into the case.
6. BULLET SEATING: Obviously, we need a new bullet and its careful insertion into the case is the last step in the reloading process.

In the following text we will use a set of two reloading dies to perform four of these six operations. Further along in reloading, you will hear of three die and even four die sets. Actually, the same four basic operations are accomplished with all these die sets. The difference is that two and three die sets combine some of the operations, whereas, a four die set accomplishes each operation separately.

LET'S GET STARTED

We assume that your cases have been checked and lubricated, and that your reloading press has been assembled and mounted according to the instructions supplied with the tool. Most all reloading presses can be assembled to function either on the up or down stroke. In the following illustrations the press is operating on the down-stroke. Screw your Full-Length Resizing Die into the head of your press, adjust it according to the instructions supplied with the die, and you are ready to commence loading.

STEP ONE

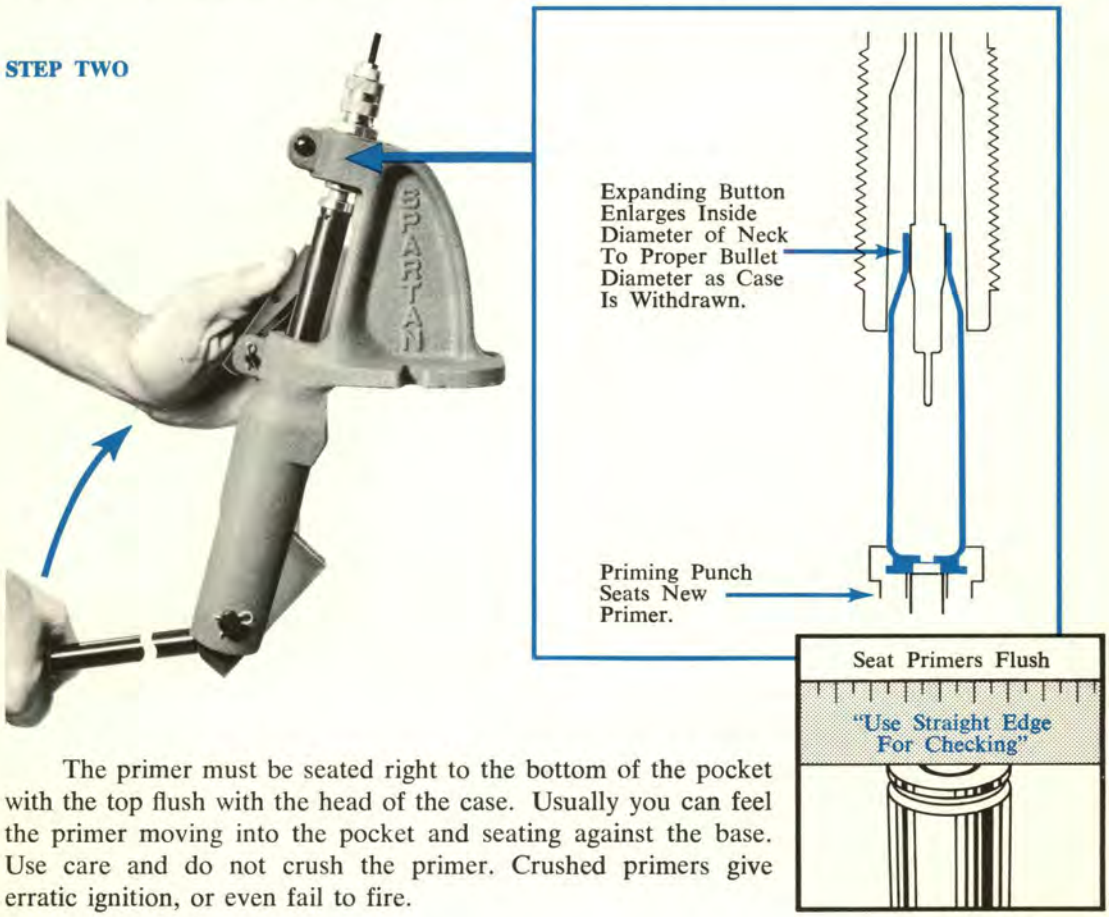


STEP ONE (Full-Length Resizing and Decapping)

Slip the head of your cartridge case into the shell holder, as shown in the illustration, and pull your press handle all the way down. If your die is adjusted properly, your entire cartridge case will enter the die flush to the shell holder. Note in the cutaway drawing how two of the original six reloading operations (full-length resizing and decapping) are accomplished by this step.

STEP TWO (Inside Neck Expanding and Priming)

As your case is withdrawn from the resizing die, two further operations are accomplished. The expanding button will automatically enlarge the neck, as pictured in the cutaway drawing, and the priming punch will seat your new primer. As the expanding action of the button is automatic, you need not be concerned with it. You must, however, place your new primer (cup side up) into the priming punch sleeve. Push the priming arm forward (toward the press) and pull up on your press handle. As the ram is lowered, the priming arm will enter the slot in the side of the ram and seat the primer.



The primer must be seated right to the bottom of the pocket with the top flush with the head of the case. Usually you can feel the primer moving into the pocket and seating against the base. Use care and do not crush the primer. Crushed primers give erratic ignition, or even fail to fire.

STEP THREE (Charging Powder)

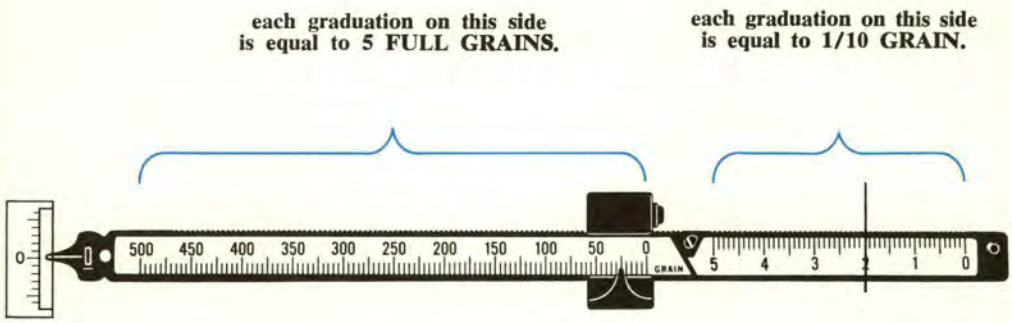
Weighing and loading the powder charge is the one operation that requires the greatest care. Not that handling modern smokeless powder is dangerous for, in fact, it is not. These powders are far less dangerous than gasoline or cleaning fluid. However, you want an accurate load and a cartridge that is safe to shoot in your rifle. Therefore, you should use every precaution in choosing and weighing your powder charge.

The data section in this Handbook specifies the powders that are appropriate for your specific cartridge and bullet weight. It also lists the suggested weight of the powder charge in grains and fractions of grains. For example, 8.5 would be read as EIGHT and FIVE-TENTHS grains. 10.0 would be read as TEN grains. Carefully level your powder scale as described in the instructions and set it to weigh your required charge. The illustration on the right indicates how to adjust your scale.

Using a spoon, slowly sprinkle small amounts of your powder into the scale pan until the beam comes into balance. The beam is in balance when the pointed end (extreme left) is exactly on the zero mark.

Carefully remove your pan and pour its contents into the cartridge case. Use your powder funnel to insure that every bit of the powder enters the case. To avoid the possibility of accidentally "DOUBLE CHARGING" a cartridge, you should develop a foolproof system of loading. A suggested method is to place all the uncharged cartridge cases on your left. As you pick up each case for charging, turn it up-side-down and shake it. This will insure that the case is empty. Turn the case right-side-up, charge it, and place it carefully on your right.

To gain the advantage of greater speed, you may eventually want to purchase a powder measure. When used in conjunction with a scale, these machines dispense powder both rapidly and accurately. A good powder measure plus a set of loading blocks, are worthwhile accessories which you should consider adding to your reloading tools. See Accessory Section for description.



This illustration shows the beam of a modern reloading scale. Note how it is graduated on both sides of the pivot point. The scale is set by moving the two weights (poise) to the proper graduations. The large poise (on the left) is used to obtain multiples of FIVE GRAINS, while the small poise (on the right) is used for FRACTIONS of a grain, or SINGLE grains from one to five.

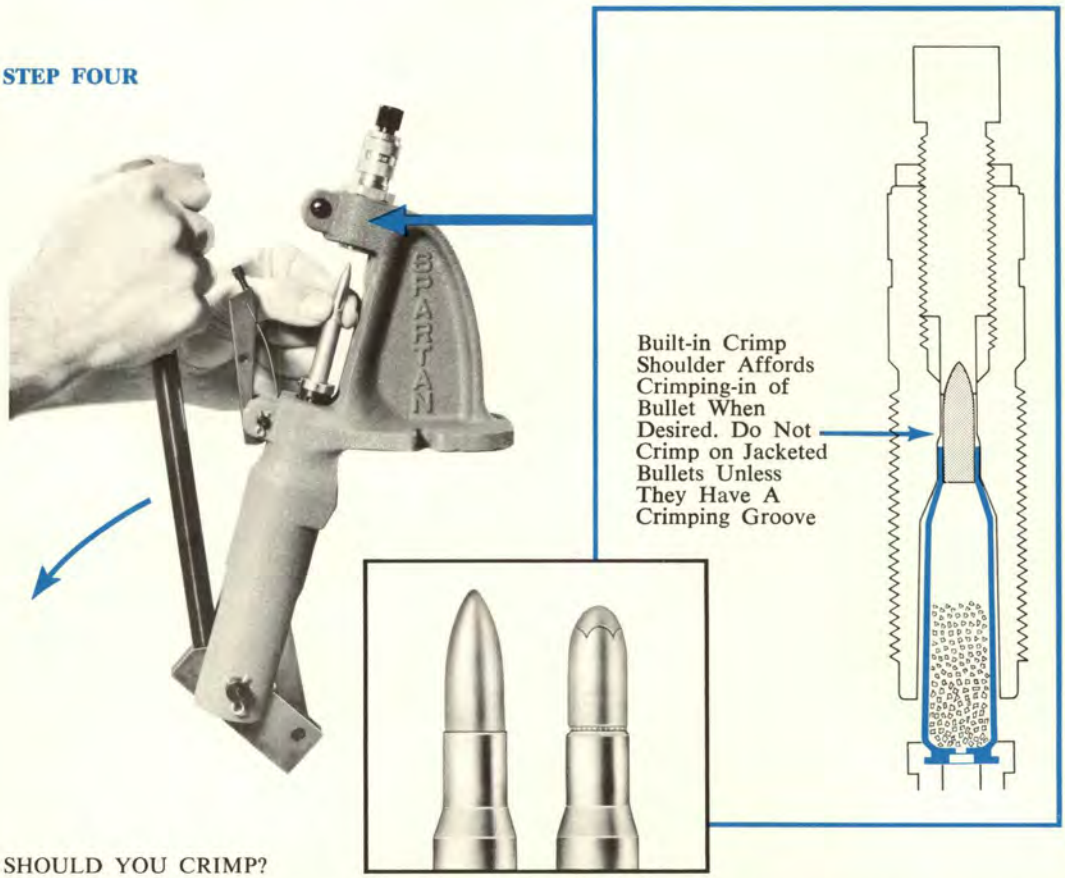
EXAMPLE: The illustration shows a setting of 27.0 grains. If you wanted to decrease this 1/10 grain, you would simply move the small poise one notch to the right.

STEP FOUR (Bullet Seating)

The last step in cartridge reloading is seating your new bullet. Make sure that the overall length of your finished round is not longer than the MAXIMUM OVERALL LENGTH listed in the Data Section. This is important because a bullet which is set too far forward will bump the rifling and build up pressure. This is explained in the Reference Section under pressure. If you have any questions as to how long your cartridges should be, compare them with an unfired factory round. It is wise to make up a sample cartridge (less powder and primer) and try it through the magazine and chamber of your rifle to insure proper functioning.

This illustration shows how a bullet is seated. Screw your bullet seating die into the head of your press and adjust it according to the instructions supplied with the die. Place a primed, charged cartridge case in the shell holder and a bullet on the mouth of the case. Pull your press handle all the way down. As the case enters the die, the bullet will be pushed firmly into the neck of the case. Adjusting the seating screw controls the depth to which the bullet is seated. Adjusting the die body controls the crimp.

STEP FOUR



SHOULD YOU CRIMP?

CRIMPING IS A MATTER OF CHOICE. ALL HUNTING LOADS WHICH WILL SEE HARD USE IN THE MAGAZINE SHOULD BE CRIMPED. BEST ACCURACY, HOWEVER, IS USUALLY OBTAINED BY NOT CRIMPING-IN THE BULLET.

This portion of the Handbook has covered the basics of rifle cartridge reloading. It is intended as a guide to help you get started. We also recommend that you read the preamble to your Data Section, along with the Reference chapters of this Handbook.

After reading this material, if you still have questions, write to the Lyman Technical Staff (see page 6). They will be glad to offer assistance.

Rifle Data

The data contained in this Handbook supersedes all previous loading data published in preceding issues of the Lyman Reloading Handbook. All data has been tested by our technicians and found to be safe when loaded with our components and fired in our test fire arms under our controlled conditions. Since the Lyman Gun Sight Corporation has no control over the actual use of this data, nor choice of the firearms and components employed, no responsibility for the use of this data is assumed.

Preamble

THE FOLLOWING ARE RECOMMENDATIONS FOR USING THIS DATA.

STARTING LOAD — It is recommended that the reader begin with the suggested weight of powder listed in this bracket and work up slowly to his best performing load. Never decrease this charge as an increase in pressure could be encountered (see pressure chapter located in reference section).

MAXIMUM LOAD — All jacketed bullet loads which are classified as maximum were tested at a safe maximum working pressure in our rifles. These loads should not be exceeded, nor should they be quickly accepted by the reader as a safe working maximum for his rifle. Read the pressure chapter located in the reference section before using these loads.

The maximum loading listed for cast lead alloy bullets, while not always representative of maximum pressure, does indicate a maximum workable velocity for the powder, bullet and caliber (see accuracy with cast bullets in reference section).

ACCURACY LOAD — As accuracy is not consistently the same with all firearms, this load requires some interpretation by the reader. Where an accuracy load is listed, it merely indicates our most accurate test results with this particular bullet weight and caliber.

Slight variations of the load may be necessary to produce optimum accuracy for your rifle. Where this load is printed in a colored panel, it indicates that the load was at, or near, a maximum pressure level. Such a load requires that the reader work up to it slowly (see pressure chapter in reference section).

FACTORY DUPLICATION LOAD — Where possible, we have listed the load which duplicated factory velocity for the bullet weight tested. It should not be assumed that this load duplicates factory pressure. Where this load is printed in a colored panel, it indicates that the load was at, or near, a maximum pressure level. Such a load requires that the reader work up to it slowly (see pressure chapter in reference section).

VELOCITIES — The velocities printed in this section were recorded at a distance of fifteen feet from the muzzle of the test firearm.

POWDERS — While a wide variety of reloading powders were used in testing loads for this Handbook, all of these powders are not listed. In all instances, however, we have listed the powders which turned in the best results in our tests.

BULLETS — The bullet chapter, located in the reference section of this Handbook, lists the various bullets used in our testing. Refering to this chapter will help you with your selection of either a cast or jacketed bullet.

.22 HORNET
(5.6 x 35 R mm)

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast..... .223-.224
Maximum Case Length ..... 1.403″
Trim-to Length ..... 1.393″
Maximum Overall Length (w/Bullet) 1.723″
Primer Size ..... Small Rifle
Lyman Shell Holder Number 4
Firearm used for Test .... Savage Model 219
Barrel Length ..... 26″ Twist ..... 1-16″

Only a few reloading powders are suitable for the 22 Hornet. Its small case capacity excludes the use of all bulky powders. Even the powders listed will not duplicate original factory ballistics. Fine accurate loads can be made, however, and reloading of this cartridge is well worthwhile. Most Hornet rifles have a groove diameter of .224. Some are encountered with .223 grooves. The reloader should take care to insure that his bullet diameter corresponds with his rifle groove. Due to the modest velocity, bullets with relatively thin jackets will expand best.

40 Grain Jacketed

*Designates a compressed powder charge.

.218 BEE

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .224"
Maximum Case Length ..... 1.345"
Trim-to Length ..... 1.335"
Maximum Overall Length (w/Bullet) 1.680"
Primer Size ..... Small Rifle
Lyman Shell Holder Number 10
Firearm used for Test .. Marlin over & under
Barrel Length ..... 26" Twist ..... 1-16"

The most uniform velocities and best accuracy with both lead and jacketed bullets was obtained when using I.M.R. 4227 powder. Do not use pointed bullets in those rifles which have tubular magazines. For positive expansion, use thin jacketed, light bullets which are designated as "hornet" bullets. Factory ballistics can not be duplicated with the powders currently available to the reloader.

.222 REMINGTON
(5.7 x 43mm)

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .224"
Maximum Case Length ..... 1.700"
Trim-to Length ..... 1.690"
Maximum Overall Length (w/Bullet) 2.130"
Primer Size ..... Small Rifle
Lyman Shell Holder Number 26
Firearm used for Test ..... Remington 700
Barrel Length ..... 24" Twist ..... 1-14"

Best results with this cartridge were obtained with I.M.R. 4198 powder. This powder turned in the most uniform velocity and accuracy with all of the jacketed bullet weights tested. I.M.R. 3031 powder also gave excellent results with jacketed bullets. All loads were tested with the new Remington 7½ primer (designed specifically for cartridges of this type).

.223 REMINGTON
(5.56mm)

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .224"
Maximum Case Length ..... 1.760"
Trim-to Length ..... 1.750"
Maximum Overall Length (w/Bullet) 2.260"
Primer Size ..... Small Rifle
Lyman Shell Holder Number 26
Firearm used for Test .. Colt AR-15 Sporter
Barrel Length ..... 20" Twist ..... 1-12"

Inasmuch as bolt action, target type rifles are not available for this cartridge, test accuracy was somewhat limited. All of the jacketed loads listed functioned perfectly through the action of our semi-auto test rifle. The only cast bullet loads that would operate the action of our test gun were maximum, or near maximum loads using I.M.R. 4227 powder. All other cast bullet loads require manual operation of the bolt. All testing was done with the new Remington 7½ primer.

.222 REMINGTON MAGNUM

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .224″
Maximum Case Length ..... 1.850″
Trim-to Length ..... 1.840″
Maximum Overall Length (w/Bullet) 2.280″
Primer Size ..... Small Rifle
Lyman Shell Holder Number 26
Firearm used for Test ..... Remington 700
Barrel Length ..... 24″ Twist ..... 1-14″

In our testing of this cartridge, results were so good that we did not list any one particular accuracy load for jacketed bullets. All jacketed bullet weights shot well with I.M.R. 4198, I.M.R. 3031 and I.M.R. 4895 powder and gave excellent accuracy. H335 powder gave fine results with 40 grain jacketed bullets, while RX7 was excellent with the 50 and 55 grain weights. The new Remington 7½ primer was used for all testing.

Firearm used for Test ..... Winchester 70
Barrel Length ..... 22″ Twist ..... 1-14″

Velocity readings in this caliber tend to be very erratic from one gun to the next. Pressures tend to jump around quite a bit. Data taken in one gun will not necessarily be uniform with results in another gun.

.224 WEATHERBY MAGNUM

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .224"
Maximum Case Length ..... 1.925"
Trim-to Length ..... 1.915"
Maximum Overall Length (w/Bullet) 2.312"
Primer Size ..... Large Rifle
Lyman Shell Holder Number 3
Firearm used for Test ..... **Weatherby Varmint Master**
Barrel Length ..... **26"** **Twist** ..... **1-14"**

In this case the use of a magnum type primer will result in very high and dangerous pressures. Use only standard large rifle primers for this cartridge. Most 40 and 45 grain bullets have jacket designs which are too thin for best results, due to premature bullet break up.

.22/250
(22 Varminter)

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .224"
Maximum Case Length ..... 1.912"
Trim-to Length ..... 1.902"
Maximum Overall Length (w/Bullet) 2.350"
Primer Size ..... Large Rifle
Lyman Shell Holder Number 2
Firearm used for Test ..... Savage 110
Barrel Length ..... 24" Twist ..... 1-14"

All of our loads for this cartridge shot extremely well. Results were so good in fact that they made the choice of the accuracy load rather difficult. For "custom" chambers (due to the wide variations in reamers used) maximum loads should be approached with extreme caution. Bullets lighter than 50 grains will probably not prove satisfactory for varmint hunting. The jackets on these light bullets are too thin for this cartridge and result in premature bullet break-up.

.220 SWIFT

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .224"
Maximum Case Length ..... 2.205"
Trim-to Length ..... 2.195"
Maximum Overall Length (w/Bullet) 2.680"
Primer Size ..... Large Rifle
Lyman Shell Holder Number 5
Firearm used for Test ..... Winchester 70
Barrel Length ..... 26" Twist ..... 1-14"

While actual factory loading for this cartridge features a 48 grain bullet, we have used a 50 grain bullet for our factory duplication load. The 2 grains difference will have no noticeable effect on trajectory, or velocities, and the 50 grain bullet is more easily obtained, 40 and 45 grain bullets are a bit light for good performance on varmint. A case trimmer will prove to be necessary if maximum or near maximum loads are used.

.22 SAVAGE HI-POWER

(5.6 x 52R mm)

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .228″
Maximum Case Length ..... 2.050″
Trim-to Length ..... 2.040″
Maximum Overall Length (w/Bullet) 2.510″
Primer Size ..... Large Rifle
Lyman Shell Holder Number 6
Firearm used for Test ..... Savage 99
Barrel Length ..... 20″ Twist ..... 1-12″

Variations in groove diameters are sometimes encountered in rifles chambered for this cartridge. Most barrels have a groove diameter of .228 while a small percentage are found with a larger groove of .229. Jacketed bullets of .228 diameter work well when used in a standard groove (.228) barrel. For oversize barrels, we recommend the use of cast lead alloy bullets (sized to the exact groove diameter).

.243 WINCHESTER

(6.2 x 52mm)

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .243″
Maximum Case Length ..... 2.045″
Trim-to Length ..... 2.035″
Maximum Overall Length (w/Bullet) 2.710″
Primer Size ..... Large Rifle
Lyman Shell Holder Number 2
Firearm used for Test ..... Winchester 70
Barrel Length ..... 22″ Twist ..... 1-10″

If your .243 rifle is imported, we recommend that you carefully check its groove diameter. We have encountered rifles with groove diameters as small as .239. When fired in these **tight groove** rifles, factory loaded .243 cartridges blew primers and even our starting loads proved **too hot**. We, therefore, advise that you consider any rifle with a groove diameter of under .241 as dangerous.

In "standard groove" domestic rifles all of the I.M.R. powders gave excellent results. For long range varmint shooting, we recommend the use of 80 or 85 grain bullets as they do not lose their velocity as rapidly as the lighter projectiles.

6MM REMINGTON
244 REMINGTON

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .243″
Maximum Case Length ..... 2.233″
Trim-to Length ..... 2.225″
Maximum Overall Length (w/Bullet) 2.825″
Primer Size ..... Large Rifle
Lyman Shell Holder Number 2
Firearm used for Test ..... Remington 700
Barrel Length ..... 22″ Twist ..... 1-9″

The only difference between the 6 M/M Remington and the .244 Remington cartridge is in the factory bullet weights which are loaded into these two cases. The cases themselves are identical except for the headstamps.

Normally, .244 rifles have a 1-12″ twist and the cartridge is factory loaded with 75 and 90 grain bullets to accommodate this rifling. The 6 M/M Remington cartridge is factory loaded with a 100 grain bullet to better accommodate the 1-9″ twist of the 6 M/M rifles.

While our listed data is interchangeable for both of these cartridges, we recommend that bullets under 90 grains be used in the .244 Remington. Bullets over 75 grains are suggested for the 6 M/M Remington.

25/20 WINCHESTER

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .257"
Maximum Case Length ..... 1.330"
Trim-to Length ..... 1.320"
Maximum Overall Length (w/Bullet) 1.592"
Primer Size ..... Small Rifle
Lyman Shell Holder Number 10
Firearm used for Test ..... Winchester 92
Barrel Length ..... 20" Twist ..... 1-14"

While I.M.R. 4198 powder proved to be the best selection for the jacketed bullets tested, our best accuracy was obtained with cast bullets. All three powders listed for cast bullets produced uniform velocity and fine accuracy.

Use only round, or flat nose bullets, in those rifles which have tubular magazines. Caution; these loads are not intended for rifles which were designed for black powder cartridges.

.256 WINCHESTER

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .257″
Maximum Case Length ..... 1.281″
Trim-to Length ..... 1.275″
Maximum Overall Length (w/Bullet) 1.590″
Primer Size ..... Small Rifle
Lyman Shell Holder Number 1
Firearm used for Test ..... Marlin 62
Barrel Length ..... 24″ Twist ..... 1-14″

Many of the rifles chambered for this cartridge have slightly oversize chambers which create a problem for the reloader. These chambers cause excessive case stretching which makes it impossible to resize brass after two or three firings.

The small case capacity of the cartridge limits suitable reloading powders to a very few. Ballistics and accuracy, however, are good.

250/3000 SAVAGE

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .257″
Maximum Case Length ..... 1.912″
Trim-to Length ..... 1.902″
Maximum Overall Length (w/Bullet) 2.515″
Primer Size ..... Large Rifle
Lyman Shell Holder Number 2
Firearm used for Test .... Custom 98 Mauser
Barrel Length ..... 24″ Twist ..... 1-14″

A good many rifles which are chambered for this cartridge have 1-10″ twist barrels. In these rifles, the 60 or 75 grain bullets will seldom give accuracy. Use heavier bullets for best results.

The Sierra 75 grain hollow point proved very accurate in our test rifle (1-14″ twist) and worked well with all powders.

.257 ROBERTS

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .257″
Maximum Case Length ..... 2.233″
Trim-to Length ..... 2.223″
Maximum Overall Length (w/Bullet) 2.775″
Primer Size ..... Large Rifle
Lyman Shell Holder Number ..... 2 or 8
Firearm used for Test .... Custom Mauser 98
Barrel Length ..... 24″ Twist ..... 1-12″

Most commercial rifles for this cartridge used a short magazine which limits overall cartridge length to 2.775″. Prevalent also was the use of a long chamber throat which gives its best results when the bullet is seated just short of touching the rifling (see "Accuracy with jacketed bullets" in reference section).

Remington and Winchester brass varies in the contour of the extractor cut and requires different shell holders. Use #2 shell holder for Remington and Peters. Use #8 shell holder for Winchester and Western.

The Sierra 75 grain hollow point bullet proved to be an exceptionally fine performer in this cartridge.

.257 WEATHERBY MAGNUM

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .257″
Maximum Case Length ..... 2.550″
Trim-to Length ..... 2.540″
Maximum Overall Length (w/Bullet) 3.250″
Primer Size ..... See Cartridge Story
Lyman Shell Holder Number 13
Firearm used for Test .... Weatherby Mark V
Barrel Length ..... 26″ Twist ..... 1-12″

The data listed for this cartridge was obtained in a Weatherby rifle and is intended **for Weatherby rifles only**. The free-boring constructed into these firearms allow higher velocities at safe working pressures. For custom rifles which are not free-bored, maximum loads should be reduced a full 5%. Even then, they should be approached with caution.

The exclusive use of Federal 215 large rifle magnum primers is recommended by Weatherby, Inc. for all jacketed bullet loads. Do not use the magnum primers, however, with cast bullet data. Cast bullet data was obtained with Remington 9½ primers.

For varmint shooting, we recommend bullet weights from 75 to 100 grains.

6.5 JAPANESE

(6.5 x 50mm Arisaka)

SPECIFICATIONS:

Bullet Dia. Jacketed ..... .264″
Bullet Dia. Cast ..... .264″ to .266″
Maximum Case Length ..... 1.988″
Trim-to Length ..... 1.978″
Maximum Overall Length (w/Bullet) 2.940″
Primer Size ..... Large Rifle
Lyman Shell Holder Number 5
Firearm used for Test
Barrel Length ..... **19″** **Japanese Service Carbine Twist** ..... **1-9″**

Norma brass was used exclusively for our testing of this cartridge. Bullets weighing 120 grains or more gave the best accuracy. Avoid bullets which are designed for the 6.5 magnum sporters as these bullets will not expand properly when fired at the more moderate velocities of the 6.5 Japanese.

A wide variation in groove diameter is common with these military rifles and we recommend that you slug your bore before reloading. If the jacketed bullet size listed, does not coincide with the groove diameter of your particular rifle, we suggest that you consider the use of a cast bullet.

6.5 ITALIAN
(6.5 x 52mm Mannlicher Carcano)

SPECIFICATIONS:

Bullet Dia. Jacketed ..... .264″
Bullet Dia. Cast ..... .264″ to .266″
Maximum Case Length ..... 2.060″
Trim-to Length ..... 2.055″
Maximum Overall Length (w/Bullet) 2.900″
Primer Size ..... Large Rifle
Lyman Shell Holder Number ..... Special
Firearm used for Test
Italian Service Carbine
Barrel Length .. 21″ Twist .. Gain Twist

Due to the wide variations in groove diameters which exist in these surplus military rifles, we suggest that you proceed with caution. Slug your bore to determine the correct bullet diameter for your rifle. See "Accuracy with cast bullets" in the reference section for information on slugging your bore. If your groove diameter is larger than .264″, you could experience gas blow-by (gas from breech due to low pressure) when using the listed starting loads with the standard bullet size. We suggest that you wear shooting glasses when working out loads and that you consider the use of cast bullets sized to the exact groove diameter of your particular rifle.

Trim-to Length ..... 2.100″
Maximum Overall Length (w/Bullet) 3.010″
Primer Size ..... Large Rifle
Lyman Shell Holder Number 28
Firearm used for Test ..... Custom Mauser
Barrel Length ..... 20″ Twist ..... 1-7½″

For our testing of this cartridge, we used Norma brass exclusively. Bullets of 120 grains, or heavier, are necessary to obtain accuracy. I.M.R. 4895 and I.M.R. 4064 powders turned in the most consistent velocities.

Better than half of the rifles which we have encountered in this caliber show signs of excessive headspace. Before using a 6.5 x 54 M/M rifle, we recommend that its headspace be checked by a competent gunsmith.

6.5 x 55mm
(Swedish)

SPECIFICATIONS:

Bullet Dia. Jacketed ..... .264″
Bullet Dia. Cast ..... .264″ to .266″
Maximum Case Length ..... 2.160″
Trim-to Length ..... 2.150″
Maximum Overall Length (w/Bullet) 3.062″
Primer Size ..... Large Rifle
Lyman Shell Holder Number 27

Firearm used for Test
Swedish Military Carbine
Barrel Length ..... 18″ Twist ..... 1-7½″

As with many foreign rifles, the groove diameter of these Swedish Carbines can vary considerably. We recommend that you slug the bore of your rifle before reloading. See "Accuracy with cast bullets" for information on slugging the bore. If the jacketed bullet size listed, does not coincide with the groove diameter of your particular rifle, we suggest that you consider the use of a cast bullet.

The factory duplication loads which we have shown for this cartridge may be somewhat misleading in that they do not coincide with the 139 gr. and 156 gr. loads offered by Norma. We have used 140 gr. and 160 gr. loads as they are most commonly reloaded.

6.5 REMINGTON MAGNUM

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .264″
Maximum Case Length ..... 2.170″
Trim-to Length ..... 2.160″
Maximum Overall Length (w/Bullet) 2.800″
Primer Size ..... See Cartridge Story
Lyman Shell Holder Number 13
Firearm used for Test ..... Remington 600
Barrel Length ..... 18½″ Twist ..... 1-9″

Jacketed loads for this cartridge seem to perform equally well with either standard or magnum large rifle primers. Remington factory ammunition uses the Remington 9½ (magnum) primer. **For cast bullet loads use only standard large rifle primers.**

In testing we used bullets up to, and including 129 grains. Bullets heavier than this would require excessively deep seating to function through the magazine.

Cast bullet loads using Unique powder were found to be very accurate.

Maximum Case Length ..... 2.500″
Trim-to Length ..... 2.490″
Maximum Overall Length (w/Bullet) 3.340″
Primer Size ..... See Cartridge Story
Lyman Shell Holder Number 13
Firearm used for Test ..... **Winchester 70**
Barrel Length ..... **24″** **Twist** ..... **1-9″**

Remington 9½M (Magnum) primers were used for all of the jacketed loads listed. Either magnum or standard large rifle primers are suitable for jacketed bullets. **For cast bullet loads use only standard large rifle primers.**

Pressures in this cartridge tend to jump suddenly and the reloader should approach maximum loads with extreme caution.

The Sierra 120 grain bullet gave excellent results as did I.M.R. 4350 and Hodgdons 4831 powder.

.270 WINCHESTER
(6.9 x 64mm)

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .277″
Maximum Case Length ..... 2.540″
Trim-to Length ..... 2.530″
Maximum Overall Length (w/Bullet) 3.340″
Primer Size ..... Large Rifle
Lyman Shell Holder Number 2
Firearm used for Test ..... Savage 110
Barrel Length..... 22″ Twist ..... 1-10″

Very slight changes in the powder charge seem to jump pressures in this cartridge. We advise that you approach maximum charges with extreme caution.

The 130 grain bullets which are available for the 270 are excellent for deer loads. Heavier bullets offer very little expansion except on larger animals.

.270 WEATHERBY MAGNUM

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .277″
Maximum Case Length ..... 2.550″
Trim-to Length ..... 2.540″
Maximum Overall Length (w/Bullet) 3.250″
Primer Size ..... See Cartridge Story
Lyman Shell Holder Number 13
Firearm used for Test .. Weatherby Mark V
Barrel Length ..... 26″ Twist ..... 1-12″

The data listed for this cartridge was obtained in a Weatherby rifle and is intended **for Weatherby rifles only.** The free-boring constructed into these firearms allow higher velocities at safe working pressures. For custom rifles which are not free-bored, maximum loads should be reduced a full 5%. Even then, they should be approached with caution.

The exclusive use of Federal 215 large rifle magnum primers is recommended by Weatherby, Inc. for all jacketed bullet loads. Do not use the magnum primers, however, with cast bullet data. Only standard large rifle primers should be used with cast bullet loads.

7mm MAUSER
(7 x 57mm)

SPECIFICATIONS:

Bullet Dia. Jacketed ..... .284″
Bullet Dia. Cast ..... .284″ to .287″
Maximum Case Length ..... 2.235″
Trim-to Length ..... 2.225″
Maximum Overall Length (w/Bullet) 3.065″
Primer Size ..... Large Rifle
Lyman Shell Holder Number 2
Firearm used for Test ..... Mauser 95
Barrel Length ..... 29″ Twist ..... 1-10″

Most 7 M/M's are imported rifles and their groove diameters can vary considerably. We recommend that you slug your barrel to determine its exact groove diameter. The "Accuracy with Cast Bullets" chapter which is located in the reference section of this Handbook will explain how this is accomplished.

.284 WINCHESTER

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .284″
Maximum Case Length ..... 2.170″
Trim-to Length ..... 2.160″
Maximum Overall Length (w/Bullet) 2.800″
Primer Size ..... Large Rifle
Lyman Shell Holder Number 2
Firearm used for Test ..... Winchester 88
Barrel Length ..... 22″ Twist ..... 1-10″

Maximum loads for individual rifles seem to vary quite a bit in this caliber. We recommend that maximum loadings be approached with caution.

Dupont's I.M.R. 4350 powder gave us our best test results. This powder proved to be superior to others in this cartridge and gave excellent accuracy.

.280 REMINGTON

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .284″
Maximum Case Length ..... 2.540″
Trim-to Length ..... 2.530″
Maximum Overall Length (w/Bullet) 3.330″
Primer Size ..... Large Rifle
Lyman Shell Holder Number 2
Firearm used for Test ..... Remington 700
Barrel Length ..... 22″ Twist ..... 1-9½″

This cartridge gave very uniform velocities and excellent accuracy with all the powders and bullets tested. Duponts I.M.R. 4350 powder had perhaps a small edge over all others as far as accuracy was concerned. Strangely enough the 150 grain factory load produced less velocity than the 165 grain factory load.

7 x 61mm SHARPE & HART

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .284″
Maximum Case Length ..... 2.402″
Trim-to Length ..... 2.392″
Maximum Overall Length (w/Bullet) 3.190″
Primer Size ..... Large Rifle
Lyman Shell Holder Number 13
Firearm used for Test: Shultz & Larsen 65DL
Barrel Length ..... 24″ Twist ..... 1-10″

The 7 x 61 M/M proved to be one of the most efficient cartridges we tested. Accuracy was good and velocities were extremely uniform. Compared to other magnum cases, this cartridge produced very high velocities with minimum amounts of powder. The rifle used for testing was free-bored. For rifles which do not have a free-bored throat, this data should be reduced a full 5%. Even then, maximum loading should be approached with caution.

The Remington 9½ primer was used in our test loads.

7mm REMINGTON MAGNUM

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .284″
Maximum Case Length ..... 2.500″
Trim-to Length ..... 2.490″
Maximum Overall Length (w/Bullet) 3.290″
Primer Size ..... See Cartridge Story
Lyman Shell Holder Number 13
Firearm used for Test ..... Savage 110
Barrel Length ..... 24″ Twist ..... 1-9½″

Dupont's I.M.R. 4064, I.M.R. 4320 and I.M.R. 4350 powders gave excellent accuracy with all of the jacketed bullets tested. Hodgdon's 4831 gave good accuracy with both 165 grain and 175 grain jacketed bullets. The Remington 9½M primer was used for all jacketed loads. Either magnum or standard large rifle primers are suitable with jacketed bullets. For cast bullet loads use only **standard** large rifle primers.

7mm WEATHERBY MAGNUM

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .284″
Maximum Case Length ..... 2.550″
Trim-to Length ..... 2.540″
Maximum Overall Length (w/Bullet) 3.260″
Primer Size ..... See Cartridge Story
Lyman Shell Holder Number 13
Firearm used for Test .. Weatherby Mark V
Barrel Length ..... 26″ Twist ..... 1-12″

The data listed for this cartridge was obtained in a Weatherby rifle and is intended **for Weatherby rifles only**. The free-boring constructed into these firearms allow higher velocities at safe working pressures. For custom rifles which are not free-bored, maximum loads should be reduced a full 5%. Even then, they should be approached with caution.

The exclusive use of Federal 215 large rifle magnum primers is recommended by Weatherby, Inc. for all jacketed bullet loads. Do not use the magnum primers, however, with cast bullet data. Only standard large rifle primers should be used with cast bullet loads.

7.35mm ITALIAN
(TERNI)

SPECIFICATIONS:

Bullet Dia. Jacketed ..... .298" & .300"
Bullet Dia. Cast ..... .299" & .301"
Maximum Case Length ..... 2.01"
Trim-to Length ..... 2.00"
Maximum Overall Length (w/Bullet) 2.755"
Primer Size ..... Large Rifle
Lyman Shell Holder Number 28

Firearm used for Test:
Italian Military Carbine
Barrel Length ..... 21" Twist ..... Gain

Here again a large variation in groove diameters exist. Match the bullet diameter as closely as possible to the groove diameter. Speer jacketed bullets are .298" diameter (150 grs.) and the Hornady bullets are .300" diameter (128 grs.). Lead bullets can be sized .299" or .301". Most actual groove diameters run between .300" and .302". Due to the relatively poor design and workmanship of these rifles, we do not recommend their use except for lead bullet shooting.

30 MI CARBINE

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .308″
Maximum Case Length ..... 1.290″
Trim-to Length ..... 1.286″
Maximum Overall Length (w/Bullet) 1.680″
Primer Size ..... Small Rifle
Lyman Shell Holder Number 19
Firearm used for Test ..... M. I. Carbine
Barrel Length .....18″ Twist ..... 1-20″

As this cartridge headspaces on the case mouth, case length is critical. Never trim cases shorter than the Trim-to-Length listed and do not crimp-in the bullet.

Our best test results with jacketed bullets was obtained with the Remington 93 grain (full metal case) 30 Luger bullet used with Dupont I.M.R. 4227 powder. The accuracy of this load was acceptable but not good.

Our best test accuracy was experienced with cast bullets using 2400 powder. While these loads proved very accurate for the rifle, they did not always function the action. For best overall results (functioning of action and accuracy) we suggest the 131 grain cast bullet with AL8 powder.

93 Grain Jacketed

Powder	Sug. Starting Grains	Velocity F.P.S.	Max. Grains	Velocity F.P.S.

303 SAVAGE

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .308″
Maximum Case Length ..... 2.015″
Trim-to Length ..... 2.010″
Maximum Overall Length (w/Bullet) 2.520″
Primer Size ..... Large Rifle
Lyman Shell Holder Number 7
Firearm used for Test ..... Savage 99
Barrel Length ..... 26″ Twist ..... 1-12″

The rifles chambered for this cartridge which we have tested, show no appreciable variation in standard (.308) groove diameter. Our consumer correspondence, however, indicates that some grooves may run a little on the large size. We suggest that you slug your barrel before reloading. Commercial jacketed bullets larger than .308 are not recommended for use with this cartridge. If your barrel requires a bullet larger than .308 diameter, we suggest the use of a cast bullet which is sized to meet your needs.

(7.62 x 51R mm)

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .308″
Maximum Case Length ..... 2.0395″
Trim-to Length ..... 2.028″
Maximum Overall Length (w/Bullet) 2.550″
Primer Size ..... Large Rifle
Lyman Shell Holder Number 6
Firearm used for Test ..... Stevens 325
Barrel Length ..... 21″ Twist ..... 1-12″

Use only blunt or round nose bullets in 30/30 rifles which have tubular magazines. This is important, for a pointed bullet could accidentally chain-fire the magazine when the rifle is under recoil. You should also crimp the bullet in place to prevent it from being pushed back into the case.

Some of the older rifles chambered for this cartridge are marked 30 W.C.F. This is an old designation for the ever popular 30/30 cartridge.

Maximum Overall Length (w/Bullet) 2.600″
Primer Size ..... Large Rifle
Lyman Shell Holder Number 2
Firearm used for Test ..... Savage 99
Barrel Length ..... 22″ Twist ..... 1-12″

Our best test results with jacketed bullets were obtained with bullets of 150 grains. All of Dupont I.M.R. powders listed for this cartridge gave excellent accuracy and uniform velocities with this bullet weight.

Best cast bullet results were obtained with the 173 grain cast bullet.

.308 WINCHESTER

(7.62 x 51mm NATO)

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .308″
Maximum Case Length ..... 2.015″
Trim-to Length ..... 2.005″
Maximum Overall Length (w/Bullet) 2.800″
Primer Size ..... Large Rifle
Lyman Shell Holder Number 2
Firearm used for Test ..... Winchester 70
Barrel Length ..... 22″ Twist ..... 1-12″

The 308 Winchester cartridge proved to be extremely accurate in our testing. Duponts I.M.R. Series powders gave uniform velocities and good accuracy with all of the bullet weights tested.

The 173 grain cast bullet gave exceptionally fine accuracy with I.M.R. 4227 powder.

Caution — If military cases are used, maximum loads should be reduced by 2 grains.

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .308″
Maximum Case Length ..... 2.314″
Trim-to Length ..... 2.304″
Maximum Overall Length (w/Bullet) 3.089″
Primer Size ..... Large Rifle
Lyman Shell Holder Number 7
Firearm used for Test ..... Krag
Barrel Length ..... 22″ Twist ..... 1-10″

Dupont I.M.R. 4350 and Hodgdon's 4831 powders gave the most uniform velocities with the jacketed bullets tested.

Excellent accuracy was obtained with cast bullets of 173 grains and heavier.

Caution — A good many Krag rifles which we have inspected show cracks around the locking lug on the bolt. Have your rifle inspected by a gunsmith before using it.

30/06

(7.62 x 63mm)

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .308
Maximum Case Length 2.494
Trim-to Length 2.484
Maximum Overall Length (with Bullet) 3.340
Primer Size ..... Large Rifle
Lyman Shell Holder Number 2
Firearm used for Test ..... Savage 110
Barrel Length ..... 22" Twist ..... 1-10"

In working for accuracy with this cartridge, the 110 grain jacketed bullet gave rather poor results. We suggest that the 130 grain jacketed bullet be used for varmint.

Best lead bullet accuracy occurred with bullets of 150 grains or heavier and with Unique, 2400 and IMR 4227 powders. Lead bullet velocities of approximately 1800 F.P.S. produced the most consistent groups. Lyman cast bullet #311291 (173 grs) gave exceptionally good results.

.300 H & H MAGNUM
(7.63 x 72mm)

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .308″
Maximum Case Length ..... 2.850″
Trim-to Length ..... 2.840″
Maximum Overall Length (w/Bullet) 3.655″
Primer Size ..... Large Rifle
Lyman Shell Holder Number 13
Firearm used for Test ..... Remington 721
Barrel Length ..... 26″ Twist ..... 1-10″

Very uniform velocities and excellent accuracy were the rule throughout our testing of this cartridge. Bullets from 150 grains up to 200 grains produced the best groups.

Our very best results were had when using the Winchester 120 primer.

.300 WINCHESTER MAGNUM

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .308″
Maximum Case Length ..... 2.620″
Trim-to Length ..... 2.610″
Maximum Overall Length (w/Bullet) 3.340″
Primer Size ..... Large Rifle
Lyman Shell Holder Number 13
Firearm used for Test ..... Winchester 70
Barrel Length ..... 24″ Twist ..... 1-10″

The Winchester 120 primer gave us our best test results with this cartridge. We, therefore, used this one primer exclusively in working up the listed data. While a magnum primer may be used with this data, the reloader should realize that slight variations in pressure and velocity will occur.

.308 NORMA
MAGNUM

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .308″
Maximum Case Length ..... 2.560″
Trim-to Length ..... 2.550″
Maximum Overall Length (w/Bullet) 3.250″
Primer Size ..... See Cartridge Story
Lyman Shell Holder Number 13
Firearm used for Test:
Schultz & Larsen 65DL
Barrel Length ..... 24″ Twist ..... 1-10″

Our test rifle had a considerable amount of free-bore. On custom rifles which are not free-bored, maximum loads should be reduced by a full 5% from those listed. Even with this reduction, such loads should be approached with caution.

While magnum primers were used with all of the jacketed bullet loads listed, we suggest that only standard large rifle primers be used with cast bullet loads.

.300 WEATHERBY MAGNUM

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .308″
Maximum Case Length ..... 2.825″
Trim-to Length ..... 2.815″
Maximum Overall Length (w/Bullet) 3.5625″
Primer Size ..... See Cartridge Story
Lyman Shell Holder Number 13
Firearm used for Test .. Weatherby Mark V
Barrel Length ..... 26″ Twist ..... 1-12″

The data listed for this cartridge was obtained in a Weatherby rifle and is intended **for Weatherby rifles only**. The free-boring constructed into these firearms allow higher velocities at safe working pressures. For custom rifles which are not free-bored, maximum loads should be reduced a full 5%. Even then, they should be approached with caution.

The exclusive use of Federal 215 large rifle magnum primers is recommended by Weatherby, Inc. for all jacketed bullet loads. Do not use the magnum primers, however, with cast bullet data. Use only stardard large rifle primers with cast bullet data.

7.62 RUSSIAN
(7.62 x 54Rmm)

SPECIFICATION:

Bullet Dia. Jacketed ..... See Cartridge Story
Bullet Dia. Cast ..... See Cartridge Story
Maximum Case Length ..... 2.114″
Trim-to Length ..... 2.105″
Maximum Overall Length (w/Bullet) 3.037″
Primer Size ..... Large Rifle
Lyman Shell Holder Number 17
Firearm used for Test:
Westinghouse/Russian
Barrel Length ..... 24″ Twist ..... 1-10″

Groove and bore dimensions of these Russian Military's vary considerably. Most rifles have a groove diameter of .310″ and for these we recommend jacketed bullets of .308″ diameter or cast bullets of .310″ diameter. Due to the limitations of the chamber size, larger bullets are not recommended even in rifles which have large diameter grooves.

In our test rifle I.M.R. 4350, powder gave very uniform velocities with all jacketed bullet weights.

7.65 ARGENTINE MAUSER

(7.65 x 53mm)

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast .311″ to .313″
Maximum Case Length ..... 2.105″
Trim-to Length ..... 2.100″
Maximum Overall Length (w/Bullet) 2.970″
Primer Size ..... Large Rifle
Lyman Shell Holder Number 2
Firearm used for Test .... Argentine Mauser
Barrel Length .... 29¼″ Twist .... 1-9.8″

A wide variation of groove diameters exist with rifles chambered for this caliber. We recommend that you slug your barrel before reloading (see "Accuracy with Cast Bullets" in reference section). Jacketed bullets are available in three diameters; .311″ (Speer and Sierra), .312″ (Hornady) .313″ (Speer). Use the jacketed bullet which most closely corresponds with your groove diameter.

For Speer or Hornady 175 grain bullets use the data listed for 180 grain bullets.

Cast bullet #311466 (155 grs.) worked well in our testing. This bullet is not recommended, however, for rifles which have groove diameters larger than .311″ as it casts rather small (.312″). Where sizing diameters exceed .311″ use #311284 (214 gr.)

.303 BRITISH

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast
See Cartridge Story
Maximum Case Length ..... 2.222″
Trim-to Length ..... 2.212″
Maximum Overall Length (w/Bullet) 3.075″
Primer Size ..... Large Rifle
Lyman Shell Holder Number 7
Firearm used for Test ..... S.M.L.E.
Barrel Length ..... 25″ Jacketed/22″ Lead
Twist ..... 1-10″

An extreme variation in groove diameters exist in rifles chambered for this cartridge. In rifles which we have checked, diameters range from .309″ to .317″. We suggest that you slug your barrel before reloading (see "Accuracy with Cast Bullets" in reference section). Jacketed bullets are available in three diameters; .311″ (Speer and Sierra), .312″ (Hornady), .313″ (Speer). Use the jacketed bullet which most closely corresponds to your groove diameter. If your groove diameter runs on the small size (under .310″) the use of jacketed bullets is not recommended at all. If your groove diameter should be large (over .314″) results will be poor.

Cast bullets should be sized as near groove diameter as possible. Bullet #311466 should not be used where a sizing diameter larger than .311″ is required.

7.7 JAPANESE

(7.7 x 58mm Arisaka)

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast
See Cartridge Story
Maximum Case Length ..... 2.269″
Trim-to Length ..... 2.260″
Maximum Overall Length (w/Bullet) 3.150″
Primer Size ..... Large Rifle
Lyman Shell Holder Number 2

Firearm used for Test:
Japanese Service Rifle
Barrel Length ..... 25″ Twist ..... 1-9.75″

An extreme variation in groove diameters exists in rifles chambered for this cartridge. In rifles which we have checked, diameters range from .310″ to .317″. We suggest that you slug your barrel before reloading (see "Accuracy with Cast Bullets" in reference section). Jacketed bullets are available in three diameters; .311″ (Speer and Sierra), .312″ (Hornady), .313″ (Speer). Use the jacketed bullet which most closely corresponds to your groove diameter. With barrels larger than .314″ results will be poor.

Due to wide variations in bullet and groove diameters, utmost care should be used when working up loads.

Cast bullets should be sized as close to groove diameter as possible.

32/20 WINCHESTER

SPECIFICATIONS:

Bullet Dia. Jacketed ..... .310″
Bullet Dia. Cast ..... .311″ to .312″
Maximum Case Length ..... 1.315″
Trim-to Length ..... 1.305″
Maximum Overall Length (w/Bullet) 1.592″
Primer Size ..... Small Rifle
Lyman Shell Holder Number 10
Firearm used for Test ..... Savage Sporter
Barrel Length .... 24½″ Twist .... 1-20″

Do not use the loads listed in rifles which were designed for Black Powder or in Handguns. For Handgun loads, see the pistol data section.

Some cartridge cases may be encountered which are actually shorter than the listed "Trim-to-length". This will cause no problems in your loading, but such cases for this cartridge should be segregated according to length because of the different adjustments which will be necessary in your bullet seating die.

Some small variations in groove diameter exists in rifles chambered for this cartridge. It is advisable to slug your barrel and size cast bullets accordingly. See "Accuracy with Cast Bullets" in reference section.

32/40

SPECIFICATIONS:

Bullet Dia. Jacketed & Cast .. .320" & .321"
Maximum Case Length ..... 2.130"
Trim-to Length ..... 2.120"
Maximum Overall Length (w/Bullet) 2.500"
Primer Size ..... Large Rifle
Lyman Shell Holder Number 6
Firearm used for Test ..... Winchester 94
Barrel Length ..... 20" Jacketed/26" Lead
Twist ..... 1-16"

Use only blunt or round nose bullets in rifles which have tubular magazines and crimp the bullets to prevent their movement. Due to the popularity of the 170 grain jacketed bullet, we have used and listed it for a factory duplication load rather than the 165 grain bullet which is normally loaded by the factories for this cartridge.

170 Grain Jacketed

32 REMINGTON

SPECIFICATIONS:

Bullet Dia. Jacketed ..... .320" to .321"
Bullet Dia. Cast ..... .319" to .321"
Maximum Case Length ..... 2.050"
Trim-to Length ..... 2.045"
Maximum Overall Length (w/Bullet) 2.525"
Primer Size ..... Large Rifle
Lyman Shell Holder Number ..... #15 or #3
Firearm used for Test ..... Remington 81
Barrel Length ..... 22" Twist ..... 1-14"

Jacketed bullets for this cartridge are available in .320" diameter (Rem.) and .321" diameter (Hornady). As we have encountered barrels as small as .319", we suggest that you slug your barrel before reloading (see "Accuracy with Cast Bullets" in reference section). For tight barrels, the smaller Remington bullet is recommended.

New brass cases which exceed the maximum case length listed may be encountered. We suggest that you check your case length before reloading and trim your case if necessary.

The Lyman #15 Shell Holder is proper for all cases with the exception of Remington brand. For Remington cases use the Lyman #3 Shell Holder.

Data listed for Unique powder will not function the action of semi-auto rifles.

8mm MAUSER
(7.9 x 57mm)

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .323″
Maximum Case Length ..... 2.240″
Trim-to Length ..... 2.235″
Maximum Overall Length (w/Bullet) 3.250″
Primer Size ..... Large Rifle
Lyman Shell Holder Number 2
Firearm used for Test ..... Mauser 98
Barrel Length ..... 23″ Twist ..... 1-9¼″

Before loading for this cartridge, we recommend that you slug your barrel (see "Accuracy with Cast Bullets" in reference section). Do not use .323″ diameter bullets in any rifle which has a groove diameter smaller than .321″.

For non-standard (small groove diameter) barrels we suggest the use of lead alloy bullets sized as near to the exact groove diameter as possible.

.338 WINCHESTER MAGNUM

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .338″
Maximum Case Length ..... 2.500″
Trim-to Length ..... 2.490″
Maximum Overall Length (w/Bullet) 3.340″
Primer Size ..... See Cartridge Story
Lyman Shell Holder Number 13
Firearm used for Test ..... Winchester 70
Barrel Length ..... 24″ Twist ..... 1-10″

Fine accuracy and uniform velocities were turned in with all of the powders and bullets tested. I.M.R. 4350 and 4831 gave exceptional results. Remington magnum primers were used in collecting jacketed data. Cast bullet loadings should be used with standard large rifle primers only.

.340 WEATHERBY MAGNUM

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .338″
Maximum Case Length ..... 2.825″
Trim-to Length ..... 2.815″
Maximum Overall Length (w/Bullet) 3.5625″
Primer Size ..... See Cartridge Story
Lyman Shell Holder Number 13
Firearm used for Test .... Weatherby Mark V
Barrel Length ..... 26″ Twist ..... 1-10″

The data listed for this cartridge was obtained in a Weatherby rifle and is intended **for Weatherby rifles only.** The free-boring constructed into these firearms allow higher velocities at safe working pressures. For custom rifles which are not free-bored, maximum loads should be reduced a full 5%. Even then, they should be approached with caution.

The exclusive use of Federal 215 large rifle magnum primers is recommended by Weatherby Inc., for all jacketed bullet loads. Do not use the magnum primers, however, with cast bullet data. Use only standard large rifle primers with lead bullets.

.351 WINCHESTER
SELF-LOADING

SPECIFICATIONS:

Bullet Dia. Jacketed ..... .351″
Bullet Dia. Cast ..... .352″
Maximum Case Length ..... 1.380″
Trim-to Length ..... 1.376″
Maximum Overall Length (w/Bullet) 1.900″
Primer Size ..... Small Rifle
Lyman Shell Holder Number 15
Firearm used for Test ..... Winchester 07
Barrel Length ..... 20″ Twist ..... 1-16″

To insure positive functioning of the action, loads must be worked up to near maximum.

348 caliber gas checks are used with cast bullets for this cartridge.

At best our test accuracy with this cartridge could only be considered as fair. Best overall results were obtained with cast bullets and I.M.R. 4227 powder.

35 REMINGTON

SPECIFICATIONS:

Bullet Dia. Jacketed ..... .358″
Bullet Dia. Cast ..... .357″ to .359″
Maximum Case Length ..... 1.920″
Trim-to Length ..... 1.910″
Maximum Overall Length (w/Bullet) 2.525″
Primer Size ..... Large Rifle
Lyman Shell Holder Number:
See Cartridge Story
Firearm used for Test ..... Marlin 336
Barrel Length ..... 20″ Twist ..... 1-16″

While a minor amount of groove variation is encountered in rifles of this caliber, .358″ diameter bullets are workable in all instances. Use only blunt, or round nose bullets, in those rifles which have tubular magazines. Bullets are best crimped in place to prevent their moving with recoil.

With cast bullets, the bullet should be sized to the exact groove diameter. If the rifle has multi or shallow groove rifling, then cast bullet velocities must be held to 1600 F.P.S. or less, if accuracy is to be obtained. See "Accuracy with Cast Bullets" in reference section for more information.

The #8 Lyman Shell Holder works on all brass with the exception of Remington and Peters brand which requires a #2.

.358 WINCHESTER
(8.8mm)

SPECIFICATIONS:

Bullet Dia. Jacketed ..... .358″
Bullet Dia. Cast ..... .358″ to .359″
Maximum Case Length ..... 2.015″
Trim-to Length ..... 2.005″
Maximum Overall Length (w/Bullet) 2.780″
Primer Size ..... Large Rifle
Lyman Shell Holder Number 2
Firearm used for Test ..... Savage 99F
Barrel Length ..... 22″ Twist ..... 1-12″

In testing this cartridge, we had rather poor results with the 150 grain bullets. Dupont I.M.R. Series powders gave very good accuracy with all of the other bullet weights.

Cast bullet accuracy with this cartridge was excellent.

.350 REMINGTON MAGNUM

SPECIFICATIONS:

Bullet Dia. Jacketed ..... .358" to .359"
Bullet Dia. Cast ..... .357" to .359"
Maximum Case Length ..... 2.170"
Trim-to Length ..... 2.160"
Maximum Overall Length (w/Bullet) 2.800"
Primer Size ..... See Cartridge Story
Lyman Shell Holder Number 13
Firearm used for Test ..... Remington 600
Barrel Length ..... 18½" Twist ..... 1-16"

Either large rifle magnum primers or standard large rifle primers may be used with the data listed for jacketed bullets. For cast bullet loads, use only the standard large rifle primer.

Due to length limitations of the rifle magazine, bullets over 250 grains proved impractical in our testing. Even bullets of 250 grains must be set rather deeply into the case if they are to function through the magazine.

Suitable reloading powders were few due to the relatively small case capacity.

.358 NORMA MAGNUM

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .358″
Maximum Case Length ..... 2.515″
Trim-to Length ..... 2.505″
Maximum Overall Length (w/Bullet) 3.270″
Primer Size ..... See Cartridge Story
Lyman Shell Holder Number 13
Firearm used for Test ..... Shultz & Larsen
Barrel Length ..... 24″ Twist ..... 1-12″

Our test rifle had a considerable amount of free-bore. On custom rifles which are not free-bored, maximum loads should be reduced by a full 5% from those listed. Even with this reduction, such loads should be approached with caution.

While magnum primers were used with all of the jacketed bullet loads listed, we suggest that only standard large rifle primers be used with cast bullet loads.

.375 H & H MAGNUM

(9.5 x 72mm)

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .375″
Maximum Case Length ..... 2.850″
Trim-to Length ..... 2.840″
Maximum Overall Length (w/Bullet) 3.600″
Primer Size ..... See Cartridge Story
Lyman Shell Holder Number 13
Firearm used for Test ..... Winchester 70
Barrel Length ..... 24″ Twist ..... 1-12″

Large rifle magnum primers were used in developing the jacketed bullet data listed. For cast bullet loads, use only standard large rifle primers. Due to heavy recoil we recommend that all hunting loads be crimped to prevent the bullet from moving. The 235 grain bullet due to its lack of a cannelure cannot be crimped into the case.

Excellent accuracy was obtained with all I.M.R. series powders.

235 Grain Jacketed

.378 WEATHERBY MAGNUM

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .375″
Maximum Case Length ..... 2.913″
Trim-to Length ..... 2.903″
Maximum Overall Length (w/Bullet) 3.690″
Primer Size ..... See Cartridge Story
Lyman Shell Holder Number 17
Firearm used for Test .. Weatherby Mark V
Barrel Length ..... 26″ Twist ..... 1-12″

The data listed for this cartridge was obtained in a Weatherby rifle and is intended **for Weatherby rifles only**. The free-boring constructed into these firearms allow higher velocities at safe working pressures. For custom rifles which are not free-bored, maximum loads should be reduced a full 5%. Even then, they should be approached with caution.

The exclusive use of Federal 215 large rifle magnum primers is recommended by Weatherby, Inc., for all jacketed bullet loads. Do not use the magnum primers, however, with cast bullet data. Use only standard large rifle primers with cast bullet data.

Due to heavy recoil we recommend that all bullets be crimped in place.

38/55 WINCHESTER

SPECIFICATIONS:

Bullet Dia. Jacketed ..... .376″
Bullet Dia. Cast ..... .377″ to .380″
Maximum Case Length ..... 2.1285″
Trim-to Length ..... 2.118″
Maximum Overall Length (w/Bullet) 2.550″
Primer Size ..... Large Rifle
Lyman Shell Holder Number 6
Firearm used for Test ..... Winchester 94
Barrel Length ..... 26″ Twist ..... 1-18″

Most of the rifles of this caliber which we have encountered show signs of excessive headspace. It is recommended that the rifle be checked by a competent gunsmith before reloading is attempted.

Slight variations in groove diameter do exist in these rifles. Where the groove diameter measures larger than .377″, the exclusive use of cast bullets is recommended for best accuracy. See "Accuracy with Cast Bullets" in reference section.

255 Grain Jacketed

Maximum Case Length ..... 1.305″
Trim-to Length ..... 1.300″
Maximum Overall Length (w/Bullet) 1.592″
Primer Size ..... Large Pistol
Lyman Shell Holder Number 14B
Firearm used for Test ..... Winchester 92
Barrel Length ..... 20″ Twist ..... 1-36″

These loads should not be used in handguns, or in rifles which were designed for black powder. For handgun loads, see pistol section of this Handbook.

Individual tolerances vary greatly in rifles chambered for this cartridge. Therefore extreme care should be used in working up maximum loads.

The cast bullet factory duplication load is listed with a bullet which is a few grains lighter than the factory jacketed load. This is due to the popularity of bullet #40143 in this caliber.

.401 WINCHESTER
SELF-LOADING

SPECIFICATIONS:

Bullet Dia. Jacketed & Cast .. .406" to .407"
Maximum Case Length ..... 1.500"
Trim-to Length ..... 1.495"
Maximum Overall Length (w/Bullet) 2.005"
Primer Size ..... Large Rifle
Lyman Shell Holder Number 2
Firearm used for Test ..... Winchester 10
Barrel Length ..... 20" Twist ..... 1-14"

Cases for this cartridge are often quite old and it is recommended that you keep your loads on the light side to avoid trouble with poor brass. Many cases are found which exceed the maximum length listed. Check your case length carefully and trim the cases if necessary.

Our best test results were obtained with the 240 grain cast bullet and I.M.R. 4227 powder.

200 Grain Jacketed

44/40 WINCHESTER

SPECIFICATIONS:

Bullet Dia. Jacketed & Cast .. .425″ to .429″
Maximum Case Length ..... 1.305″
Trim-to Length ..... 1.300″
Maximum Overall Length (w/Bullet) 1.592″
Primer Size ..... Large Pistol
Lyman Shell Holder Number 14B
Firearm used for Test ..... Winchester 92
Barrel Length ..... 24″ Twist ..... 1-20″

These loads should not be used in handguns or in rifles which were designed for black powder. For handgun loads see pistol section in this Handbook.

Individual tolerances vary greatly in rifles chambered for this cartridge. Therefore, extreme care should be used in working up maximum loads.

Due to variations in groove diameters, it is recommended that you slug your barrel before reloading. Jacketed bullets that have a diameter of within .001″ (+ or —) of the actual groove diameter will work well.

Dupont I.M.R. 4227 powder gave us our most consistent test results.

200 Grain Jacketed

Powder	Sug. Starting Grains	Velocity F.P.S.	Max. Grains	Velocity F.P.S.

.44 REMINGTON MAGNUM

SPECIFICATIONS:

Bullet Dia. Jacketed & Cast .. .429″ to .431″
Maximum Case Length ..... 1.285″
Trim-to Length ..... 1.280″
Max. Overall Length (w/Jack. Bullet) 1.610″
Primer Size ..... Large Pistol
Lyman Shell Holder Number 7
Firearm used for Test ..... Marlin 336
Barrel Length ..... 20″ Twist ..... 1-38″

For best results in the Ruger Carbine use only jacketed bullets. Cast and half jacket bullets tend to foul the gas piston and create accuracy problems. Be certain that your primers are seated correctly. A high primer can fire the cartridge before the bolt is in locked position on the Ruger Carbine.

In rifles with multi or shallow groove rifling cast bullet velocity should be held to 1600 F.P.S., or less, for best accuracy.

The overall cartridge length listed in the specifications is for jacketed bullets only. In order to correctly seat cast bullets this length must be exceeded and the cast bullet data takes this into consideration.

Use the following lengths for cast bullets:

Overall length with bullet #429215 — 1.645″
Overall length with bullet #429360 — 1.672″
Overall length with bullet #429244 — 1.690″

.444 MARLIN

SPECIFICATIONS:

Bullet Dia. Jacketed & Cast .. .429″ to .431″
Maximum Case Length ..... 2.225″
Trim-to Length ..... 2.220″
Max. Overall Length (w/Jack. Bullet) 2.570″
Primer Size ..... Large Rifle
Lyman Shell Holder Number 14B
Firearm used for Test ..... Marlin 444
Barrel Length ..... 24″ Twist ..... 1-38″

Many of the loads listed for this cartridge are heavily compressed. When using these loads it is essential that your bullet seating die be in absolute perfect adjustment. If the case neck does not align exactly with the crimping groove in the bullet, your cases will bulge, or crush, in loading.

The overall cartridge length listed in the specifications is for jacketed bullets only. In order to correctly seat cast bullets, they must exceed this length somewhat. The cast bullet data takes this into consideration and the following overall lengths are correct for the cast bullets listed.

Overall length with bullet #429215 — 2.595″
Overall length with bullet #429360 — 2.572″
Overall length with bullet #429244 — 2.620″

Our best test accuracy was obtained with bullet #429215.

45/70 GOVERNMENT
1873 SPRINGFIELD
(Trap Door Models)

SPECIFICATIONS:

Bullet Dia. Jacketed & Cast .. .457″ & .458″
Maximum Case Length ..... 2.105″
Trim-to Length ..... 2.100″
Maximum Overall Length (w/Bullet) 2.550″
Primer Size ..... Large Rifle
Lyman Shell Holder Number 17
Firearm used for Test ..... Springfield
Barrel Length ..... 32½″ Twist ..... 1-22″

These loadings are intended for single shot 45/70 rifles which have trap door actions. Do not use the loads listed for the 1886 Winchester in these rifles.

Due to the soft steel used in many of these old guns, jacketed bullet loads tend to erode the barrel. Cast bullets will be kinder to your barrel and will probably prove to be more accurate than jacketed bullets.

Firearm used for Test ..... Winchester 70
Barrel Length ..... 22″ Twist ..... 1-14″

Our best test results were obtained when using the Winchester 120 primer.

Reloading die adjustments are critical with the heavily compressed loads. If the crimping and seating screw adjustments are not exactly on the bullet cannelure, the case will be dented or crushed in loading.

405 Grain Jacketed

.460 WEATHERBY MAGNUM

SPECIFICATIONS:

Bullet Dia. Jacketed & Cast .. .457″ to .459″
Maximum Case Length ..... 2.913″
Trim-to Length ..... 2.903″
Maximum Overall Length (w/Bullet) 3.750″
Primer Size ..... See Cartridge Story
Lyman Shell Holder Number 17
Firearm used for Test .. Weatherby Mark V
Barrel Length ..... 26″ Twist ..... 1-16″

The data listed for this cartridge was obtained in a Weatherby rifle and is intended **for Weatherby rifles only**. The free-boring constructed into these firearms allow higher velocities at safe working pressures. For custom rifles which are not free-bored, maximum loads should be reduced a full 5%. Even then, they should be approached with caution.

The exclusive use of Federal 215 large rifle magnum primers is recommended by Weatherby Inc., for all jacketed bullet loads. Do not use the magnum primers, however, with cast bullet data. Use only standard large rifle primers with cast bullets.

Due to the heavy recoil of these rifles all bullets should be crimped in place.

500 Grain Jacketed

Powder	Sug. Starting Grains	Velocity F.P.S.	Max. Grains	Velocity F.P.S.
IMR 3031	86.0	2183	96.0	2444

NOTE — Loads shown in colored panels are maximum. These loads may be dangerous in your rifle, read preamble before using.

*Designates a compressed powder charge.

Lyman

GUN SIGHT CORPORATION

LYMAN METALLIC SIGHTS • RELOADING TOOLS • LYMAN TELESCOPIC SIGHTS • SHOTGUN CHOKES

MIDDLEFIELD • CONNECTICUT

Dear Fellow Shooter:

No effort has been spared in making, this #44th Edition of the Lyman Handbook, the most useful reloading guide ever published.

All in all, over 60,000 rounds of ammunition were loaded and fired in more than 150 firearms during two years of testing. All these loads were very closely checked for velocity and pressures. Accuracy results with each load was carefully noted. Those loads which were finally selected as 'accuracy loads' were the very best developed in our test guns.

However, we are fully aware of the endless number of possible combinations that will, no doubt, give excellent accuracy. Here is where you can be of assistance to your fellow shooters.

Lyman would like to hear about your proven accuracy loads; provided of course, they fall between our suggested starting loads and our maximum listings. We will make every attempt to include these loads in future handbooks. Complete details of your load would be required, including pertinent information such as, brand name of components, number of rounds fired, and firearms used.

Your general comments on this handbook will also enable us to continue to fill your needs and desires in future handbooks.

Good Shooting

THE LYMAN GUN SIGHT CORPORATION

Edward A. Matunas

Edward A. Matunas
Ballistic & Reloading Technician

Reloading Pistol Cartridges

This chapter is devoted to the basic mechanics of reloading a pistol cartridge. We urge the beginner to read it carefully and to also read the preamble to his data section before attempting to reload. The preamble, located at the beginning of each data section is intended to help you interpret this data and insure its correct use.

CHOOSING YOUR TOOLS

The basic reloading tools needed by the pistol shooter differ little from those used by the rifle enthusiast. Both require a reloading press, a set of quality dies, a powder scale and a few minor accessories. The major difference is that the pistol reloader needs more ammunition to participate in his sport. While a hundred rounds of ammo will supply a very lively afternoon of varmint or target shooting for the rifleman, a like number of rounds will merely whet the shooting appetite of the average pistol man. Consequently, the pistol shooter should be able to turn out cartridges at a fairly rapid rate.

If your pistol reloading is to be geared to quantity output, you will probably want to take advantage of all the speed features offered by the tools and accessories that are available. Not that your initial investment must include a lot of accessory items. You should, however, take into consideration your future needs when making your first purchase.

For the illustrations and text of this section of the Handbook, we have chosen only basic tools. The turret press is shown because of the greater speed it will contribute to your future loading. To gain the full speed potential of this machine, other accessories such as a primer feed, and a powder measure may be added later.

TURRET RELOADING PRESS
Speed of operation should be considered when selecting a reloading press. Pictured is the Lyman Spar-T*.

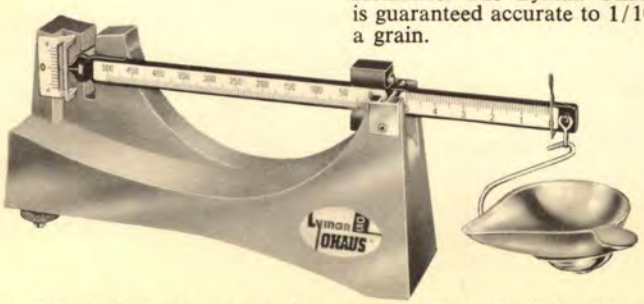
RAM, SHELL HOLDER & PRIMING ARM
These items are required to complete your press. Items shown are Lyman Spartan*.

POWDER FUNNEL

CHAMFERING REAMER

SIZING LUBRICANT

POWDER SCALE
A reliable and accurate scale is required for both safety and performance. The Lyman Ohaus D5 is guaranteed accurate to 1/10th of a grain.

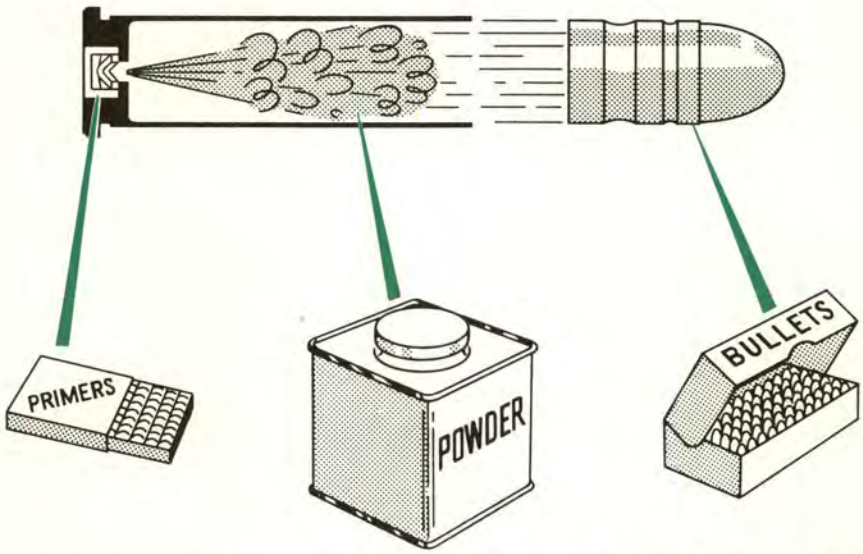


RELOADING DIE SETS
Quality reloading dies are a must. The set shown here is Lyman All-American*.

*Spar-T Sets which include the Spar-T Press, Ram, Shell Holder and Priming Arm, plus a complete set of All-American Dies are available. For complete information and prices, see the Catalog Section in the back of this Handbook.

CHOOSING YOUR COMPONENTS

When a cartridge is fired, three of the necessary components or parts of the original cartridge are used up. They are: (1) the primer. (2) the powder. (3) the bullet. Before this cartridge can be fired again, you must replace these components by reloading.



To select the proper components for your cartridge, turn to the Data page in this Handbook which lists data for your cartridge. Make a note of your correct primer size and bullet diameter. You will need to know these sizes when you purchase components.

At this time you must also decide on your powder charge and bullet weight. We suggest that you select a bullet weight with which you are familiar, and that you begin by loading the starting load listed for this bullet weight. Most dealers who handle reloading components can supply ready made bullets of the correct diameter and weight for your handgun. Later on you may wish to increase your savings and enjoyment by casting and sizing your own bullets. Complete information on making your own bullets is covered in the Reference Section under Accuracy With Cast Bullets.

GATHERING AND PREPARING CASES

You can always recognize a reloader by his almost fanatical quest for spent cartridges. He not only pockets each round that he fires, but he develops the habits of a pack rat in his zeal to con extra brass from his shooting associates. There is no mystery in his strange behavior. He simply has learned that cartridge brass is valuable, that he can turn it into extra shooting pleasure and save many dollars besides.

Regardless of the source from which you obtain your first cartridge cases, it is wise to separate them into lots and to keep a record of their history. For example, if you purchase

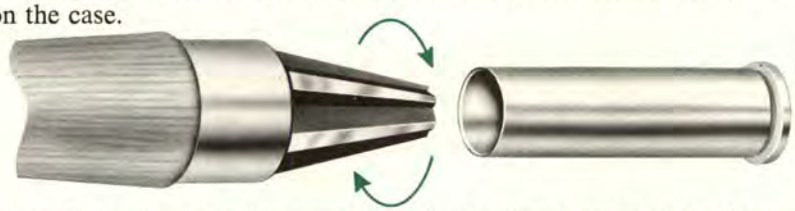
two boxes of leaded factory cartridges on a certain date, keep all one hundred rounds together and load them as one lot. Maintaining a record of the date of purchase and the number of times you loaded these cases will be helpful in determining your CASE LIFE, and you will benefit later when *TRIMMING is required.

*Trimming is necessary when your cases have lengthened after numerous firings. The trimming of cases is not covered here in the beginner section. See reference section on Cases for complete coverage.

Before each reloading check your cases for splits, or cracks about the necks and body. These cracks are indications of deteriorated brass probably due to excessive reloading. Reject all cases which show signs of defects, but before you discard them, flatten them with a pair of pliers to prevent their being used again.

Cracks and splits around the neck or body are indications of deteriorated brass probably due to excessive reloading.

You should remove the burrs from the mouth of the case after the first firing. This operation is called CHAMFERING and the small commercial hand reamer does the job easily and with uniformity. Hold your case in one hand while you lightly turn the reamer in the case mouth with the other hand. Remove very little case material and DO NOT cut a sharp knife edge on the case.



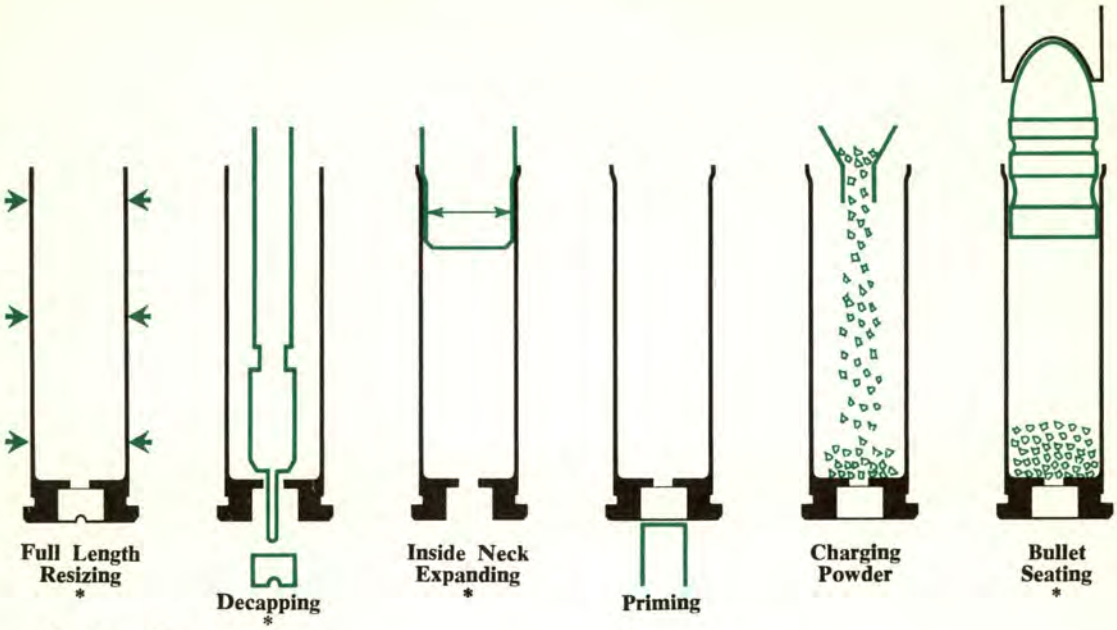
The last operation in preparing your cases for loading is to lubricate them with a suitable lubricant. This prevents the case from sticking in the resizing die and it removes dirt, or grit that might have collected. Wipe your cases carefully with a rag *SPARINGLY greased with Lyman Size-Ezy Lubricant and your cases are ready for loading. After reloading and before firing, always wipe your cases to remove the sizing lubricant.

*Too much lubricant will cause lube dents in the case when sizing. Cases dented in this manner may be used as the dents disappear on firing. It is not considered good reloading practice, however, and care should be taken.

MAKING CARTRIDGES

Putting a cartridge together is really a series of SIX very basic mechanical operations. Four of these six operations are performed by your reloading dies.

Let's first understand why these six operations are necessary to reload a pistol cartridge.



*Performed by your dies.

1. FULL LENGTH RESIZING: When a cartridge is fired, the brass walls of the case swell to the chamber size of the handgun. These walls remain pretty much at their expanded size and do not snap back to their original dimensions. Since all pistol chambers are not identical, cases fired in one pistol may not chamber in another. Even the chambers of a revolver cylinder will, in fact, vary from one to another. For this reason it is necessary to compress the walls of the case to a standard diameter which is acceptable to all handguns. This operation is called resizing.

2. DECAPPING: This operation is simply knocking out the old or fired primer.

3. INSIDE NECK EXPANDING: After the resizing operation, the neck of the case will be too small to accept the bullet. Inside neck expanding enlarges the inside diameter of the neck to a size which will receive and hold the bullet securely. For pistol cartridges, a two-step expanding plug is used to open up the inside of the case neck. The first step on this plug is slightly smaller than bullet diameter, while the second step is a few thousandths larger. The idea behind this is to allow the bullet to enter the case freely without shaving lead. The actual difference between the two steps is not visually apparent. The illustrations have been exaggerated for purposes of clarification.

4. PRIMING: This operation is simply inserting a new primer into the case.

5. INSERTING POWDER: This operation is merely weighing out and pouring a suitable charge of powder into the case.

6. BULLET SEATING: Obviously, we need a new bullet and its careful insertion into the case is the last step in the reloading process.

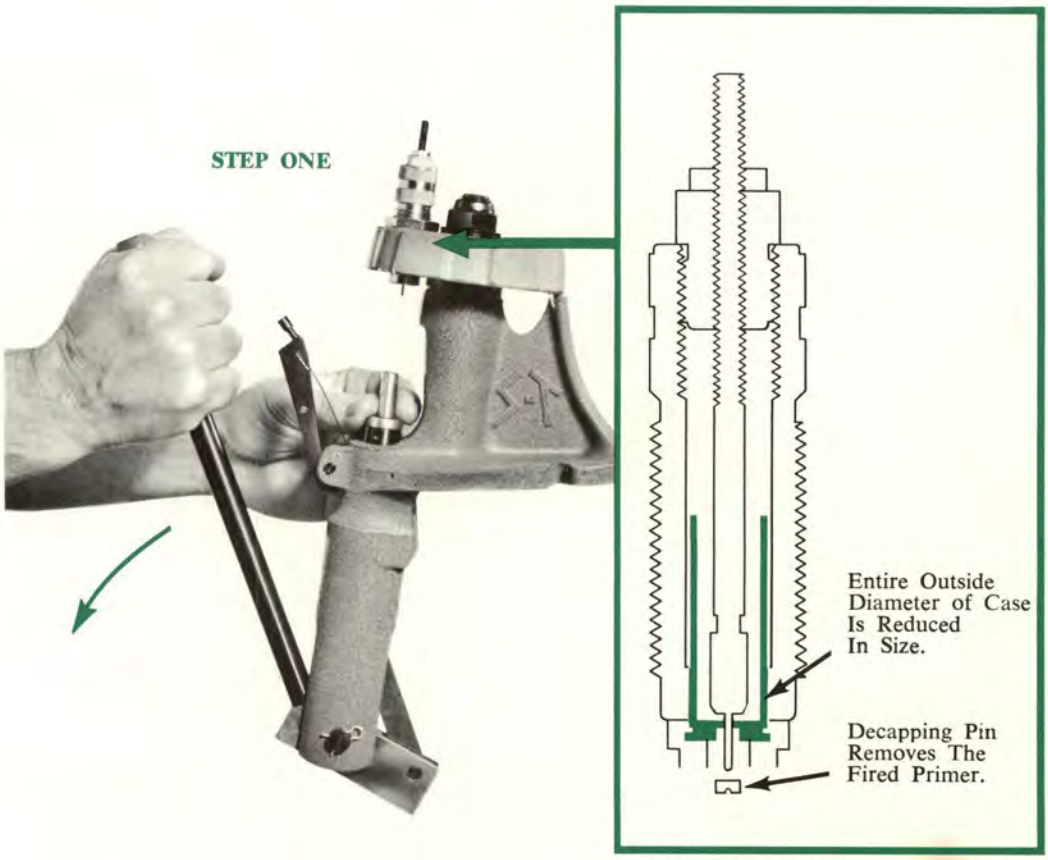
In the following text we will use a set of three reloading dies to perform four of the six operations. Further along in reloading you will hear of two-die sets and even four-die sets. Actually, the same basic operations are accomplished with all of these die sets. The difference is that two and three die sets combine some of the operations, while a four die set performs each operation separately. Because of their shape, most all pistol cartridges require the use of a three or four die set.

LET'S GET STARTED

We assume that your cases have been checked and lubricated, and that your reloading press has been assembled and mounted according to the instructions supplied with the tool. Most all reloading presses can be assembled to function either on the up, or down-stroke. In the following illustrations, the press is operating on the down-stroke. Now screw your Full Length Resizing Die into the head of your press and adjust it according to the instructions supplied with the die, and you are ready to start loading.

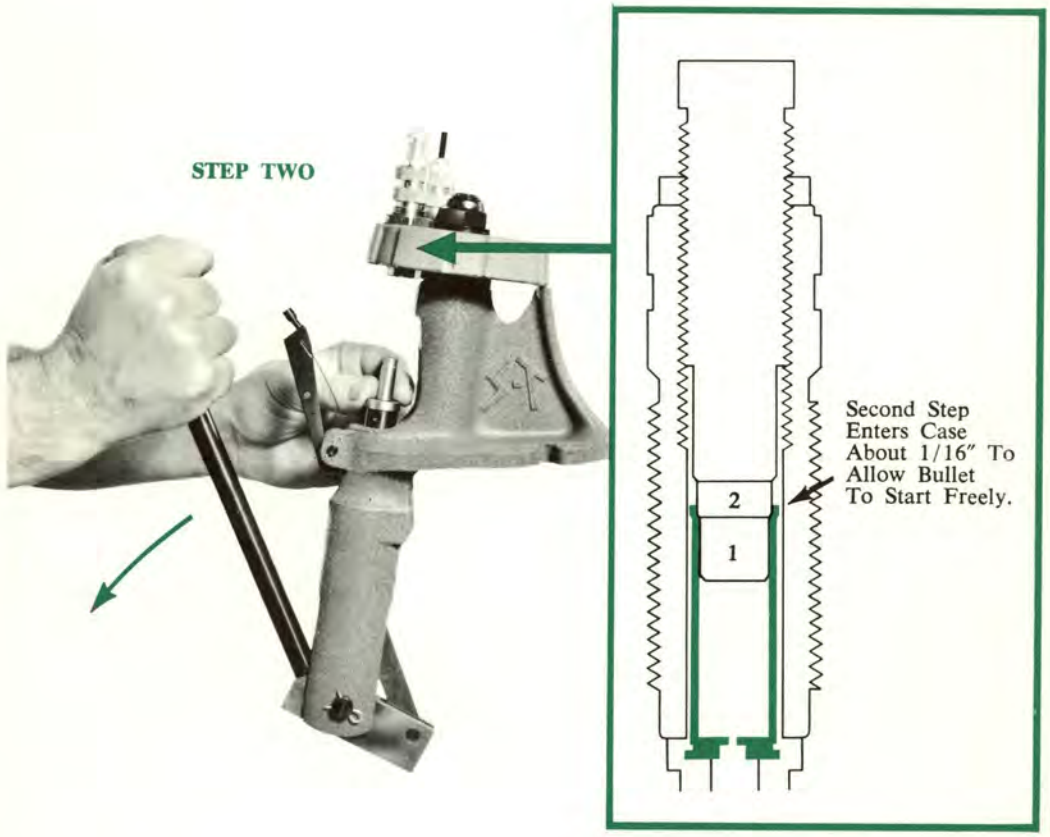
STEP ONE (Full-Length Resizing and Decapping)

Slip the head of your cartridge case into the shell holder, as shown in the illustration, and pull your press handle all the way down. If your die is adjusted correctly, your entire cartridge will enter the die flush to the shell holder. Note on the cutaway drawing how two of the original six reloading operations (full-length resizing and decapping) are accomplished by this step. Pull up on the press handle to remove your case from the die, and turn the turret head to the next station.



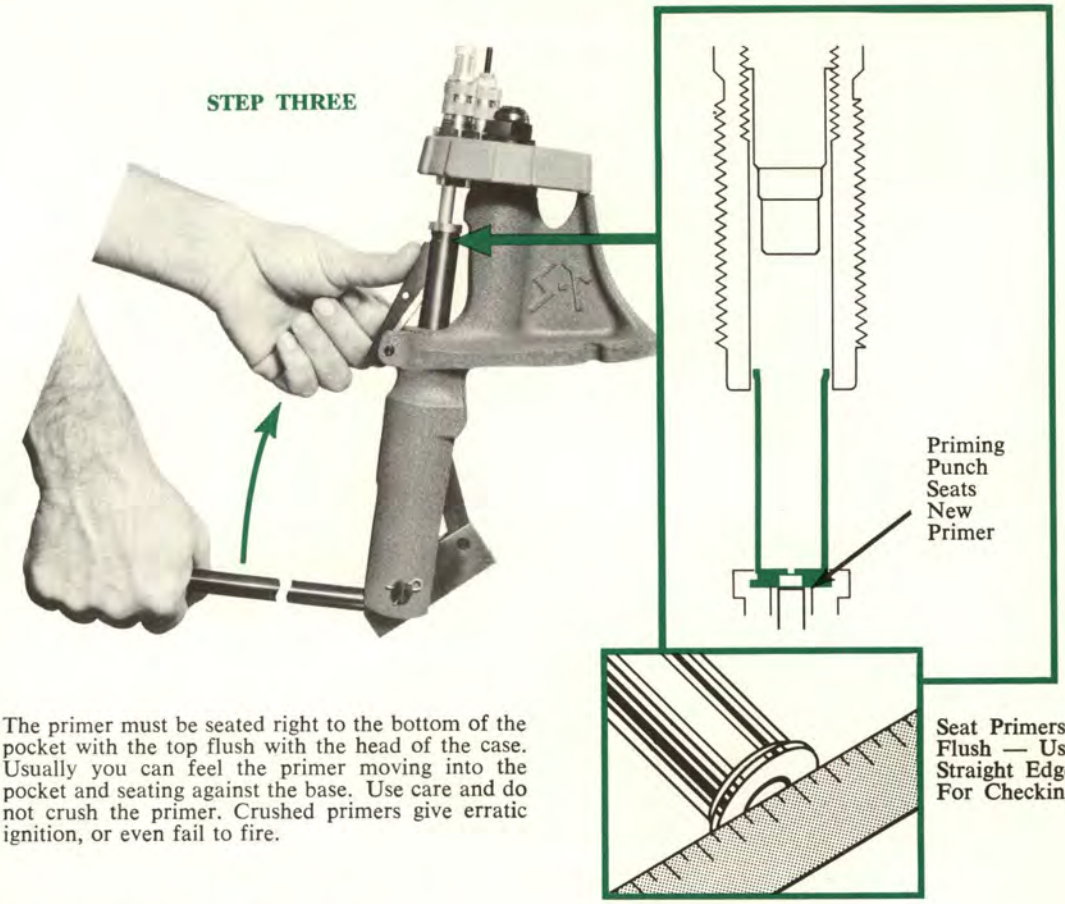
STEP TWO (Inside Neck Expanding)

Screw the Neck Expanding Die into the turret head and adjust it according to the instructions supplied with the die. Place your resized cartridge case into the shell holder and pull down on the press handle. Note in the cutaway drawing how the two-step plug enters and expands the case neck. Actually, there is only a few thousandths difference in diameter between the first and second step on the plug. This difference is not visually apparent. The illustration has been exaggerated for clarification.



STEP THREE (Priming)

The priming operation is accomplished as your case is withdrawn from the Neck Expanding Die. Place your new primer (cup side up) into the priming punch sleeve. Push the primer arm forward (toward the press) and pull up on the press handle. As the ram is lowered, the priming arm will enter the slot in the side of the ram and seat the primer.

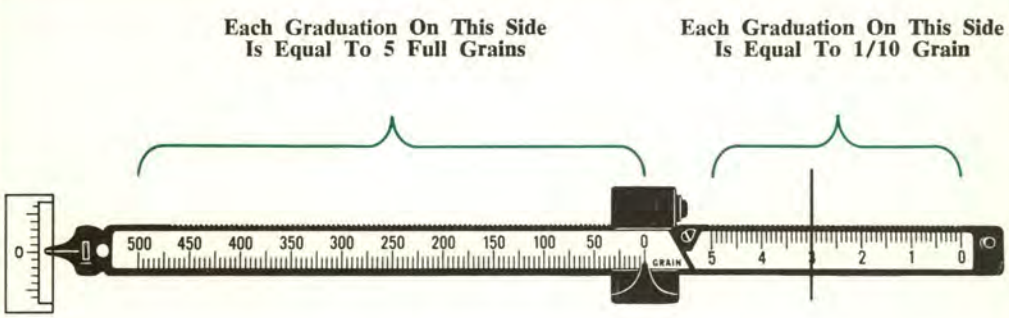


The primer must be seated right to the bottom of the pocket with the top flush with the head of the case. Usually you can feel the primer moving into the pocket and seating against the base. Use care and do not crush the primer. Crushed primers give erratic ignition, or even fail to fire.

STEP FOUR (Charging Powder)

Weighing and loading the powder charge is the one operation that requires the greatest care. Not that handling and storing modern smokeless powders is dangerous for, in fact, it is not. Working with modern powders is far less dangerous than handling gasoline, or cleaning fluid. You do want an accurate load, however, and you do want a cartridge that is safe to shoot in your handgun. Therefore, you must use care in choosing and weighing your powder charge.

The data listed in this Handbook shows the powders that are appropriate for your specific cartridge and bullet weight. It also lists the suggested weight of the powder charge in grains and fractions of grains. For example, 3.2 would be read as THREE and TWO TENTHS grains. 5.0 would be read as FIVE grains. Carefully level your powder scale according to the instructions that were packed with it, and set it to weigh your required charge. The illustration on the right shows how to adjust the scale.



The illustration shows the beam of a modern reloading scale. Note how it is graduated on both sides of the pivot point. The scale is set by moving the two weights (poise) to the proper graduations. The large poise (on the left) is used to obtain multiples of FIVE GRAINS, while the small poise (on the right) is used for FRACTIONS of a grain or SINGLE grains from one to five.

EXAMPLE: The illustration shows a setting of 3.0 grains. If you wish to increase this to 8.0 grains, simply move the large poise one notch to the left.

Using a spoon, slowly sprinkle small amounts of the powder into the scale pan until the beam comes into balance. The beam is in balance when the pointed end (extreme left) is exactly on the zero mark.

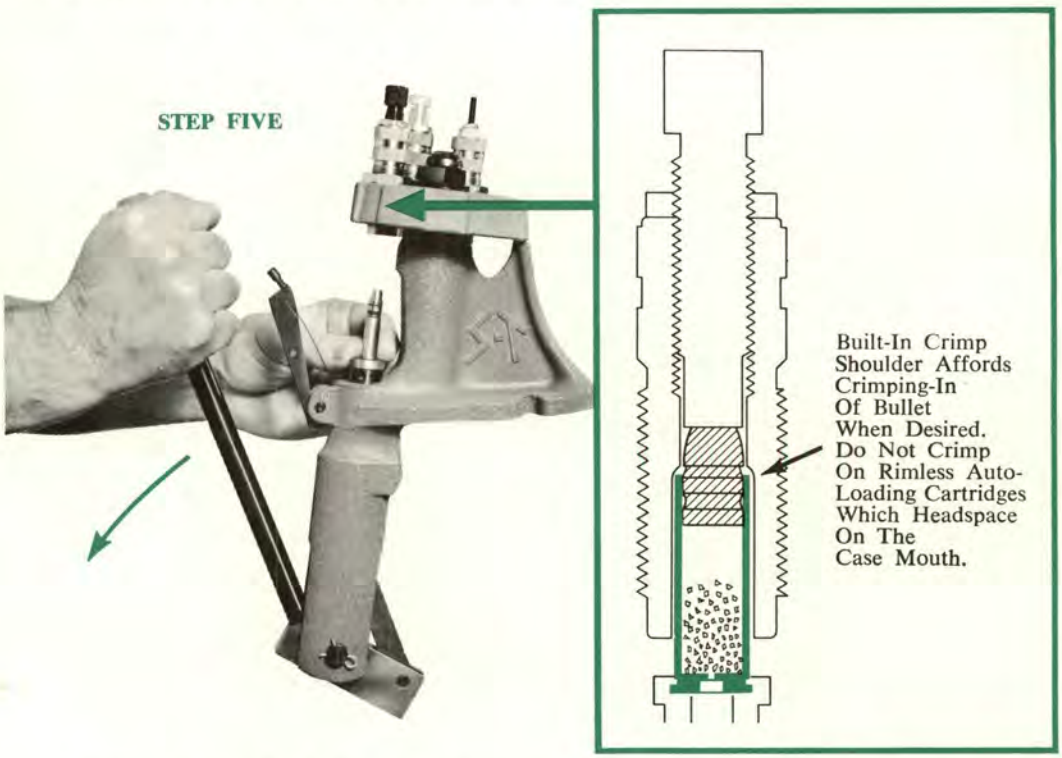
Carefully remove the pan and pour its contents into the cartridge case. Use the powder funnel to make sure that every bit of the powder enters the case. To avoid accidentally "DOUBLE CHARGING" a cartridge, you should develop a foolproof system of loading. A suggested method is to place all the uncharged cartridge cases on your left. As you pick up each case for charging, turn it up-side-down and shake it. This will insure that the case is empty. Turn the case right-side-up, charge it ,and place it carefully on your right.

To gain the advantage of greater speed, you may wish to purchase a powder measure. When used in conjunction with a scale, these machines dispense powder both rapidly and accurately.

STEP FIVE (Bullet Seating)

The last step in cartridge reloading is seating your new bullet. Make sure that the overall length of your finished round is not longer than the MAXIMUM OVERALL LENGTH listed in the Data section. This is important because a bullet that is set too far forward will not function properly in the magazine of your handgun. In revolvers, a long round will stop the cylinder from rotating. If you have any questions as to how long your cartridge should be, compare them with an unfired factory round. It is always wise to make up a sample cartridge (less powder and primer) and try it through the magazine or cylinder of your pistol to insure proper functioning.

The illustration shows how a bullet is seated. Screw the bullet seating die into the head of the press and adjust it according to the instructions supplied with the die. Place a primed, charged cartridge case in the shell holder and start a bullet in the mouth of the case. Pull the press handle all the way down. As the case enters the die, the bullet is pushed firmly into the neck of the case. Adjusting the seating screw controls the depth to which the bullet is seated. Adjusting the die body controls the crimp. Do not crimp on rimless auto-loading cartridges such as 45 Auto, 380 Auto, 9 M/M Luger or any case which headspaces on the mouth. On all other pistol cases, a crimp may be used if desired. Magnum cartridges, due to their heavy recoil, require the use of a crimp to hold the bullet securely.



This portion of the Handbook has covered the basics in pistol cartridge reloading. It is intended as a guide to help you get started. We also recommend that you read the preamble to your Data Section along with the Reference chapters of the Handbook.

After reading this material, if you still have questions, write to the Lyman Technical Staff (see page 6). They will be glad to offer assistance.

Pistol Data

The data contained in this Handbook supersedes all previous loading data published in preceding issues of the Lyman Reloading Handbook. All data has been tested by our technicians and found to be safe when loaded with our components and fired in our test fire arms under our controlled conditions. Since the Lyman Gun Sight Corporation has no control over the actual use of this data, nor choice of the firearms and components employed, no responsibility for the use of this data is assumed.

Preamble

THE FOLLOWING ARE RECOMMENDATIONS FOR USING THIS DATA.

STARTING LOAD — It is recommended that the reader begin with the suggested weight of powder listed in this bracket and work up slowly to his best performing load. Never decrease this charge as an increase in pressure could be encountered (see pressure chapter located in reference section).

MAXIMUM LOAD — All jacketed bullet loads which are classified as maximum were tested at a safe maximum working pressure in our firearms. These loads should not be exceeded, nor should they be quickly accepted by the reader as a safe working maximum for his pistol. Read the pressure chapter located in the reference section before using these loads.

The maximum loading listed for cast lead alloy bullets, while not always representative of maximum pressure, does indicate a maximum workable velocity for the powder, bullet and caliber (see accuracy with cast bullets in reference section).

ACCURACY LOAD — As accuracy is not consistently the same with all firearms, this load requires some interpretation by the reader. Where an accuracy load is listed, it merely indicates our most accurate test results with this particular bullet weight and caliber.

Slight variations of the load may be necessary to produce optimum accuracy for your pistol. Where this load is printed in a colored panel, it indicates that the load was at, or near, a maximum pressure level. Such a load requires that the reader work up to it slowly (see pressure chapter in reference section).

FACTORY DUPLICATION LOAD — Where possible, we have listed the load which duplicated factory velocity for the bullet weight tested. It should not be assumed that this load duplicates factory pressure. Where this load is printed in a colored panel, it indicates that the load was at, or near, a maximum pressure level. Such a load requires that the reader work up to it slowly (see pressure chapter in reference section).

VELOCITIES — The velocities printed in this section were recorded at a distance of fifteen feet from the muzzle of the test firearm.

POWDERS — While a wide variety of reloading powders were used in testing loads for this Handbook, all of these powders are not listed. In all instances, however, we have listed the powders which turned in the best results in our tests.

BULLETS — The bullet chapter, located in the reference section of this Handbook, lists the various bullets used in our testing. Refering to this chapter will help you with your selection of either a cast or jacketed bullet.

.22 REMINGTON JET

SPECIFICATIONS:

Bullet Dia. Jacketed & Cast .. .222″ to .223″
Maximum Case Length ..... 1.288″
Trim-to Length ..... 1.283″
Maximum Overall Length (w/Bullet) 1.659″
Primer Size ..... Small Rifle
Lyman Shell Holder Number 1
Firearm used for Test ..... Smith & Wesson
Barrel Length ..... 6″ Twist ..... 1-15″

To insure proper extraction and functioning of the cylinder, remove all traces of lubricant from both cases and cylinder before firing. Standard .224″ diameter bullets which are normally used in 22 caliber guns are not for use in this cartridge. Use .222 diameter or .223 diameter bullets only.

40 Grain Jacketed

Powder	Sug. Starting Grains	Velocity F.P.S.	Max. Grains	Velocity F.P.S.

Accuracy Load:
IMR 4227 Powder, 13.0 Grains, 1992 F.P.S.

NOTE — Loads shown in colored panels are maximum. These loads may be dangerous in your pistol, read preamble before using.

*Designates a compressed powder charge.

.221 REMINGTON FIREBALL

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .224″
Maximum Case Length ..... 1.400″
Trim-to Length ..... 1.395″
Maximum Overall Length (w/Bullet) 1.830″
Primer Size ..... Small Rifle
Lyman Shell Holder Number 26
Firearm used for Test .... Remington XP100
Barrel Length .. 10-13/16″ Twist .. 1-12″

Very uniform velocities were obtained with this cartridge. Accuracy with I.M.R. 4198 powder and all jacketed bullets was excellent.

Accuracy with cast bullets, while not on par with jacketed bullet accuracy, was also good.

Firearm used for Test ..... Luger
Barrel Length .... 3¾" Twist .... 1-9.85"

With some pistols the listed starting loads may fail to function the action. Heavier loads, however, should be worked up to cautiously.

On cast bullet #313249, the case should be crimped on the leading edge of the first driving band. Some variations in groove diameters exist with these pistols and the barrel should be slugged for best results. Size cast bullets as near to exact groove diameter as possible.

.30 MAUSER
(7.63mm Mauser)

SPECIFICATIONS:

Bullet Dia. Jacketed & Cast .. .309″ to .311″
Maximum Case Length ..... .990″
Trim-to Length ..... .985″
Maximum Overall Length (w/Bullet) 1.381″
Primer Size ..... Small Pistol
Lyman Shell Holder Number 12
Firearm used for Test ..... Mauser Military
Barrel Length ..... 5½″ Twist ..... 1-8″

A fair amount of groove diameter variation exists in handguns of this caliber. We suggest that you slug your barrel before reloading. Jacketed bullets larger than .309″ are not recommended. If your barrel slugs larger than .309″, we suggest the use of cast bullets sized as close as possible to exact groove diameter.

85 Grain Jacketed

.32 A.C.P.
(7.65mm Browning)

SPECIFICATIONS:

Bullet Dia. Jacketed & Cast .. .308" to .312"
Maximum Case Length ..... .680"
Trim-to Length ..... .672"
Maximum Overall Length (w/Bullet) .984"
Primer Size ..... Small Pistol
Lyman Shell Holder Number 23
Firearm used for Test ..... Mauser HSC
Barrel Length ..... 3" Twist ..... 1-16"

A wide variation in groove diameters is present in handguns of this caliber. The loads listed may be used with .311" jacketed bullets in pistols which have a groove diameter as small as .309".

Our test accuracy with all bullets (cast and jacketed) was generally poor.

71 Grain Jacketed

Powder	Sug. Starting Grains	Velocity F.P.S.	Max. Grains	Velocity F.P.S.
Bullseye	1.5	603	2.2	825
Red Dot	1.7	705	2.5	937

.32 SMITH & WESSON

SPECIFICATIONS:

Bullet Dia. Cast ..... .310" to .313"
Maximum Case Length ..... .605"
Trim-to Length ..... .600"
Maximum Overall Length (w/Bullet) .930"
Primer Size ..... Small Pistol
Lyman Shell Holder Number 9
Firearm used for Test .. Smith & Wesson 30
Barrel Length ..... 3" Twist ..... 1-18¾"

Maximum loads are intended for solid frame revolvers only and should be used with caution.

For top break revolvers (if gun is in good condition) use the suggested starting loads. Do not go higher as these pistols are of a relatively weak design.

Some variations in groove diameter are encountered in handguns chambered for this cartridge. Slug your barrel before reloading and size your cast bullets to as near groove diameter as possible.

9mm LUGER

(9mm Parabellum)

SPECIFICATIONS:

Bullet Dia. Jacketed & Cast .. .354" to .356"
Maximum Case Length ..... .754"
Trim-to Length ..... .751"
Maximum Overall Length (w/Bullet) 1.169"
Primer Size ..... Small Pistol
Lyman Shell Holder Number 12
Firearm used for Test .. Smith & Wesson 39
Barrel Length ..... 4" Twist ..... 1-10"

The 9mm Luger cartridge headspaces on the case mouth. For this reason, the case should not be crimped and the trim-to-length should be adhered to closely. A short case, or a crimp on the mouth, can cause headspace problems.

While slight variations in groove diameters are encountered with pistols for this cartridge, most guns have a groove diameter of .354". Jacketed bullets of .355" can safely be used in all barrels ranging from .354" to .356".

.357 MAGNUM

SPECIFICATIONS:

Bullet Dia. Jacketed & Cast .. .356″ to .358″
Maximum Case Length ..... 1.290″
Trim-to Length ..... 1.285″
Maximum Overall Length (w/Bullet) 1.590″
Primer Size ..... Small Pistol
Lyman Shell Holder Number 1
Firearm used for Test .. Smith & Wesson 27
Barrel Length ..... 5″ Twist ..... 1-18¾″

Depending upon their manufacture, some variation in groove diameter exists in these handguns. It is wise to slug your barrel before reloading and size cast bullets to exact groove diameter.

In order to hold your maximum overall length to below 1.590″, it is sometimes necessary to crimp cast bullets on the forward edge of the first driving band.

Velocities for half-jacketed bullets must be kept above 750 F.P.S. to prevent jackets from lodging in the barrel.

.380 AUTO

(9mm Corto)
(9mm Short)

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .355″
Maximum Case Length ..... .680″
Trim-to Length ..... .677″
Maximum Overall Length (w/Bullet) .984″
Primer Size ..... Small Pistol
Lyman Shell Holder Number 26
Firearm used for Test ..... Husqvarna
Barrel Length ..... 5″ Twist ..... 1-16″

While a wide variation in groove diameters exists (as large as .362″) in pistols chambered for this cartridge, the use of bullets larger than .355″ is usually not possible, this is due to the chamber and case dimensions.

A large diameter bullet will bulge the case to the point where the cartridge will not chamber. If the groove diameter of your pistol runs on the large size, accuracy will be poor and there is little you can do about it.

Heavier cast bullets of .355″ diameter will sometimes cause a slight case bulge with some lots of brass. This is due to inside case taper and so long as the cartridge will chamber and function it can be ignored.

.38 SUPER AUTO

SPECIFICATIONS:

Bullet Dia. Jacketed & Cast .. .354″ to .356″
Maximum Case Length ..... .900″
Trim-to Length ..... .895″
Maximum Overall Length (w/Bullet) 1.280″
Primer Size ..... Small Pistol
Lyman Shell Holder Number 12
Firearm used for Test ..... Colt
Barrel Length ..... 5″ Twist ..... 1-16″

These loads are intended only for guns which are chambered for the "Super Auto" cartridge.

For the "Standard 38 Auto" cartridge, it is recommended that you reduce the starting load by 1/2 grain and work up to the listed starting load. In these pistols, use only loads which call for bullets of 133 grains or less.

As this cartridge headspaces on the rim, it may be crimped if desired.

.38 SPECIAL

SPECIFICATIONS:

Bullet Dia. Jacketed & Cast .. .355″ to .359″
Maximum Case Length ..... 1.155″
Trim-to Length ..... 1.149″
Maximum Overall Length (w/Bullet) 1.550″
Primer Size ..... Small Pistol
Lyman Shell Holder Number 1
Firearm used for Test .. Smith & Wesson 14
Barrel Length ..... 6″ Twist ..... 1-18¾″

Occasionally handguns of various makes and models will vary from the groove diameters listed. It is wise to slug your barrel before selecting a sizing die. Size cast bullets to as near actual groove diameter as possible.

Cast bullet #358430 (in both 150 and 195 gr. weights) must exceed maximum overall length by .005″ to be seated correctly. All loads listed for this bullet take this extra length into consideration. We have used this bullet in its 195 grain weight for a 200 grain factory duplication load. This is due to the popularity of the particular bullet rather than an oversight.

Velocities for half-jacketed bullets must be kept to at least 725 F.P.S. to prevent jackets from lodging in the barrel. If a crimp is desired on a half jacketed bullet, it should be placed at the junction of the lead and the jacket.

.38 SMITH & WESSON

(380 MK1)
(38 Colt New Police)

SPECIFICATIONS:

Bullet Dia. Cast ..... .354" to .360"
Maximum Case Length ..... .775"
Trim-to Length ..... .765"
Maximum Overall Length (w/Bullet) 1.180"
Primer Size ..... Small Pistol
Lyman Shell Holder Number 21
Firearm used for Test ..... Smith & Wesson
Barrel Length ..... 4" Twist ..... 1-18¾"

These loads are intended only for solid frame revolvers which are in good condition.

As wide variations in groove diameters occur in guns chambered for this cartridge, we suggest that you slug your barrel before reloading. Bullets should be sized to as near groove diameter as possible.

38/40 WINCHESTER

SPECIFICATIONS:

Bullet Dia. Jacketed ..... .400″
Bullet Dia. Cast ..... .400″ to .401″
Maximum Case Length ..... 1.305″
Trim-to Length ..... 1.300″
Maximum Overall Length (w/Bullet) 1.592″
Primer Size ..... Large Pistol
Lyman Shell Holder Number 14B
Firearm used for Test ..... Colt S.A.A.
Barrel Length ..... 7½″ Twist ..... 1-36″

These loads are not to be used in handguns which were designed for black powder.

A great many revolvers which are chambered for this cartridge have groove and bore dimensions which are so far oversize that it is impossible to obtain accuracy. The chamber dimensions limit the diameter of the bullet and nothing can be done to make these oversize barrels shoot well.

180 Grain Jacketed

Powder	Sug. Starting Grains	Velocity F.P.S.	Max. Grains	Velocity F.P.S.

.41 MAGNUM

SPECIFICATIONS:

Bullet Dia. Jacketed and Cast ..... .410″
Maximum Case Length ..... 1.290″
Trim-to Length ..... 1.285″
Maximum Overall Length (w/Bullet) 1.590″
Primer Size ..... Large Pistol
Lyman Shell Holder Number 30
Firearm used for Test .. Smith & Wesson 57
Barrel Length ..... 6″ Twist ..... 1-18¾″

Our test results with this cartridge were excellent. Very uniform velocities and fine accuracy was obtained with all of the loads listed.

Correct seating of some cast bullets require that you exceed the maximum overall length listed. The proper overall lengths with these bullets are listed below. All data listed for these specific bullets takes this extra length into consideration.

Overall length with bullet #41032 — 1.663″
Overall length with bullet #41028 — 1.595″
Overall length with bullet #41026 — 1.720″

44/40 WINCHESTER

SPECIFICATIONS:

Bullet Dia. Jacketed & Cast .. .425″ to .429″
Maximum Case Length ..... 1.305″
Trim-to Length ..... 1.300″
Maximum Overall Length (w/Bullet) 1.592″
Primer Size ..... Large Pistol
Lyman Shell Holder Number 14B
Firearm used for Test ..... Colt S.A.A.
Barrel Length ..... 7½″ Twist ..... 1-20″

These loads are not to be used in handguns which were designed for black powder.

As a wide variation in groove diameters exist with handguns chambered for this cartridge, it is recommended that you slug your barrel. Size cast bullets as near to actual groove diameter as possible.

Jacketed bullets which are within .001″ of the groove diameter can be used successfully.

200 Grain Jacketed

Powder	Sug. Starting Grains	Velocity F.P.S.	Max. Grains	Velocity F.P.S.
Bullseye	5.0	790	6.7	965
Unique	8.0	825	11.1	1125

205 Grain Cast
BULLET #42798 (#2 ALLOY)

.45 A.C.P.

SPECIFICATIONS:

Bullet Dia. Jacketed & Cast .. .450″ to .453″
Maximum Case Length ..... .898″
Trim-to Length ..... .895″
Maximum Overall Length (w/Bullet) 1.275″
Primer Size ..... Large Pistol
Lyman Shell Holder Number 2
Firearm used for Test .. Colt, Gov't. Model
Barrel Length ..... 5″ Twist ..... 1-16″

As this cartridge headspaces on the case mouth, the trim-to-length must be adhered to closely and the case should not be crimped. A short case, or a crimp on the case mouth, can cause headspace problems.

While groove dimensions for these handguns will vary from .450″ to .453″ the reloader will sometimes have difficulty if he uses a bullet over .451″ diameter. Maximum case and chamber dimensions usually provide for a bullet of .451″ and larger bullets may bulge cases to the point where they fail to chamber.

Most pistols (unless they are altered) will not feed wad cutter type bullets such as #452389 and #452460. This also applies to the 185 grain jacketed wad cutter.

.45 COLT

SPECIFICATIONS:

Bullet Dia. Jacketed & Cast .. .450″ to .454″
Maximum Case Length ..... 1.285″
Trim-to Length ..... 1.280″
Maximum Overall Length (w/Bullet) 1.600″
Primer Size ..... Large Pistol
Lyman Shell Holder Number 11
Firearm used for Test ..... Colt S.A.
Barrel Length ..... 5½″ Twist ..... 1-16″

Pre-World War II model revolvers normally have a groove diameter of .454″, while post war models usually run .451″. It is wise to slug your barrel and size cast bullets to as near the exact diameter as possible.

In order to adhere to the maximum overall length listed, the seating depth of some cast bullets must be watched closely. Bullet #454190 should be seated to crimp on the ogive. Bullet #454424 should be seated to crimp on the forward edge of the first driving band.

If a crimp is desired on half-jacketed bullets, it should be placed at the junction of the jacket and lead nose.

Lyman

GUN SIGHT CORPORATION

LYMAN METALLIC SIGHTS • RELOADING TOOLS • LYMAN TELESCOPIC SIGHTS • SHOTGUN CHOKES

MIDDLEFIELD • CONNECTICUT

Dear Fellow Shooter:

No effort has been spared in making, this #44th Edition of the Lyman Handbook, the most useful reloading guide ever published.

All in all, over 60,000 rounds of ammunition were loaded and fired in more than 150 firearms during two years of testing. All these loads were very closely checked for velocity and pressures. Accuracy results with each load was carefully noted. Those loads which were finally selected as 'accuracy loads' were the very best developed in our test guns.

However, we are fully aware of the endless number of possible combinations that will, no doubt, give excellent accuracy. Here is where you can be of assistance to your fellow shooters.

Lyman would like to hear about your proven accuracy loads; provided of course, they fall between our suggested starting loads and our maximum listings. We will make every attempt to include these loads in future handbooks. Complete details of your load would be required, including pertinent information such as, brand name of components, number of rounds fired, and firearms used.

Your general comments on this handbook will also enable us to continue to fill your needs and desires in future handbooks.

Good Shooting

THE LYMAN GUN SIGHT CORPORATION

Edward A. Matunas

Edward A. Matunas
Ballistic & Reloading Technician

Loading Shotshells

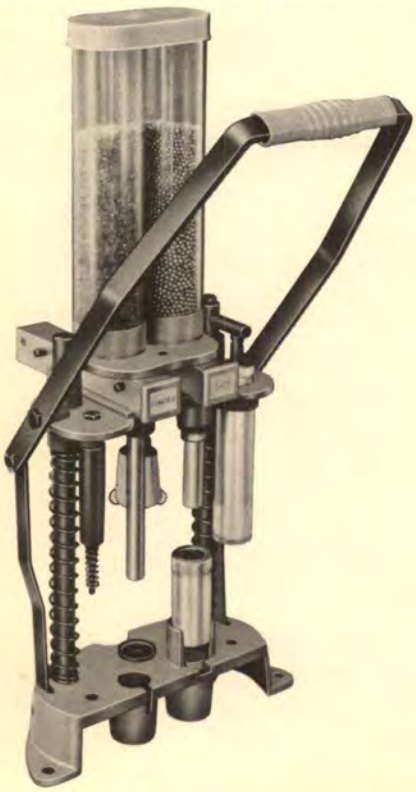
This chapter is devoted to the basic mechanics of reloading shotshells. We urge the beginner to read it carefully and to also read the preamble to his data section before attempting to reload. The preamble, located at the beginning of each data section is intended to help you interpret this data and insure its correct use.

CHOOSING YOUR LOADER

Selecting a reloading machine can be pretty confusing to the average beginner because these units are available in such a wide variety of designs and at a wide range in prices. Starting as low as $12.50 for a hand type tool, and going as high as $300.00 for a super progressive, the novice is offered a maze of features for which he is expected to "pay his money and take his choice". Unfortunately, at this stage of the game, the beginner is not sure of his requirements and he has difficulty in interpreting the advertised features of each machine.

To help simplify this problem let us analyze for a moment just what it is that you pay for in a shotshell machine. Obviously, all machines are identical in at least one manner: **They all load shotshells.** How well, how fast and how easy they will do this is what you are actually buying. Unlike a metallic cartridge reloading press, most shotshell machines are a package deal. That is, they come complete with a set of reloading dies, a powder measure and a shot measure. Consequently, the starting price of the average good shotshell machine may appear high in comparison to the starting price of the rifle cartridge press. If you consider the additional equipment that is included with the shotshell machine, you are not actually paying more.

The beginner needs a reloader that is easy to understand and simple to operate. Many shotshell reloading machines come completely assembled and adjusted. This is a worthwhile feature for getting started with the least amount of fuss.



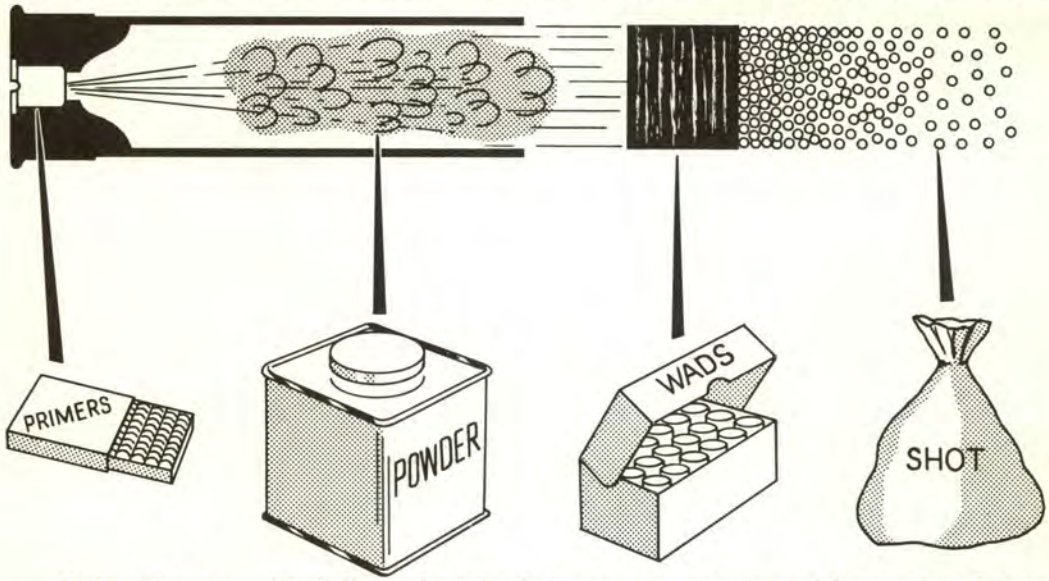
The main factor that causes the difference in prices between shotshell reloading machines is **reloading speed**. Moderately priced loaders are completely manual operated. A single shotshell case is moved by hand through a sequence of loading procedures. Although such machines are usually the simplest to use, they do have the slowest rate of production.

The progressive reloader is much faster, but it is also more expensive and slightly more complicated. It processes a number of cases at one time — turning them out at a very respectable hourly rate. As the operator must pull the press handle and feed cartridges into the machine, some progressive units are partially manual. Others are available that provide various stages of automatic operation.

For the instructional text and illustrations in this chapter, we have selected the Lyman Easy Shotshell Loader (production rate—240 shells per hour).

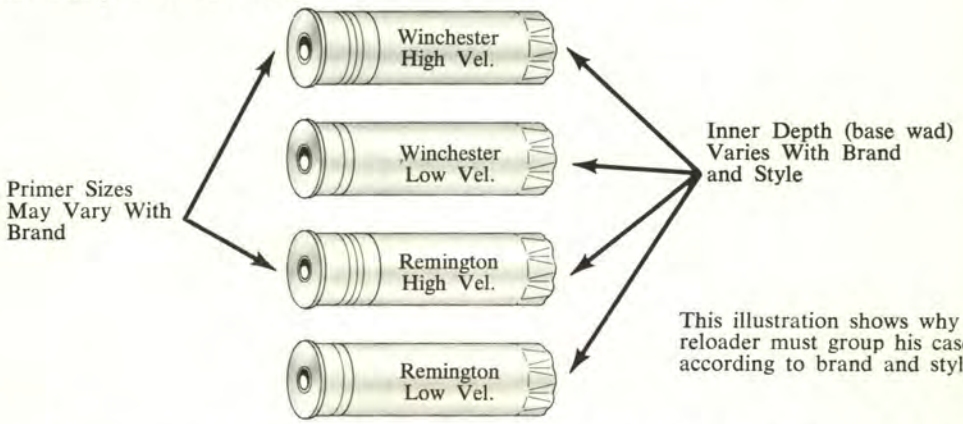
BUYING THE PROPER COMPONENTS

When you fire a shotshell four components, or parts, of the original cartridge are used up. They are: 1. The PRIMER. 2. The POWDER. 3. The WADS. 4. The SHOT.



Before the same shotshell can be reloaded, new components must be purchased to replace those expended in firing.

The key to selecting proper components lies in the fired shotshell casing. The inner dimensions of the cases vary with brand and style of shell. If you are to reload a shotshell successfully, you must be able to identify your casing and pick a loading for that particular case. You cannot mix cases of various brands and styles and hope to load them successfully with the same primers and wads.



This illustration shows why a reloader must group his cases according to brand and style.

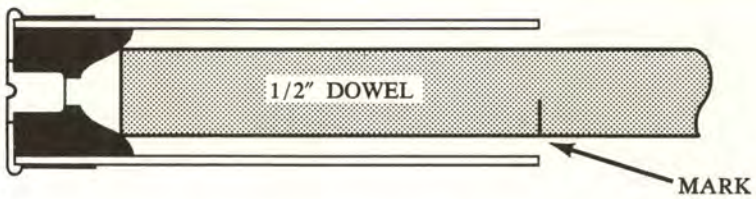
To choose your components turn to the Data Page in the Handbook which lists loads for your gauge. From the variety of loads shown, pick the one that fits your requirements. For example, if you wish a 12 gauge 2-3/4″ field load, choose loads in this bracket that list your casing. The Data Page will also give the correct primer size and a suggested shot size for your casing.

GATHERING AND PREPARING YOUR CASES

Most hand-loaders depend on new factory loaded ammo as a source for their cases. After the new cartridges have been fired, the casings are saved and put carefully away for future reloading. They should be stored in a moderately warm, clean area that is as free from dampness as possible. A moisture proof box is the best place to store both plastic and paper cases. This keeps them clean and dry.

Form the habit of inspecting your cases carefully before each reloading. It is the mark of a professional reloader and the only way to produce quality handloads for your scatter gun.

Sort the cases by brand and style — this is a must! Only cases of the same brand and style can be loaded as a group. Check each case for defects in the inner base wad as explained in the following illustration.



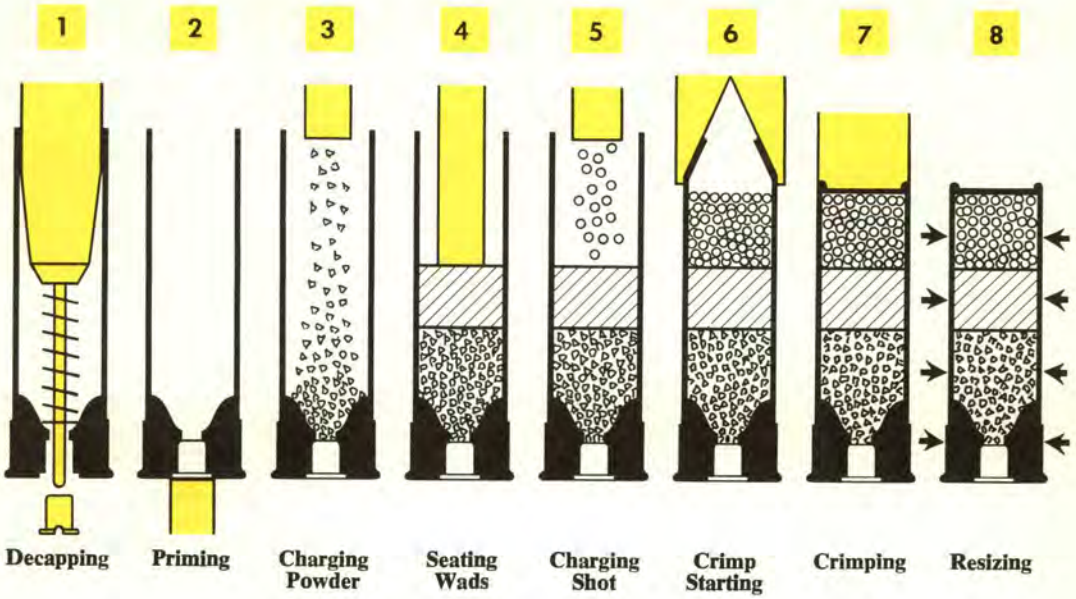
The dark area in the illustration is the **inner base wad**. Portions of the wad are sometimes blown out or destroyed, when the cartridge is fired. Good reloading requires that the inner base wad be intact. To check for defects in the inner base wad, make a simple depth gauge from a piece of ½" dowel. Insert the dowel in a new or once fired case and mark it at the case mouth. If your cases are all of the same brand and style (as they should be), this gauge can be used to check all the cases of the lot. Discard any that vary in depth.

Assuming that the cases are of one group and that they have passed the inner base wad test, let's continue with the inspection:

1. Discard any cases that are bent or badly deformed.
2. Check to see if the crimp that holds the plastic tube (or paper) to the metal has loosened. Discard the loose ones.
3. Discard any cases that show cracks, holes or tears.

MAKING SHOTSHELLS

Putting a shotshell together is really a series of eight very basic mechanical operations. When you view the operations collectively, as shown in the illustration, they may appear somewhat complicated and tedious to enact. Actually, they are not difficult. The eight operations are performed in a series of five simple steps that are really quite easy and, in fact, rather fun.



Let's first understand each of these operations and find out why they are necessary to reload a shotshell:

1. DECAPPING

This operation is simply knocking out the old or fired primer.

2. PRIMING

This operation is merely inserting a new primer into the case.

3. CHARGING POWDER

On most present day shotshell machines, the powder measure is an integral part of the tool and is designed to drop a fixed charge. A powder bushing, which is inserted in the measure, controls the amount of powder it throws.

4. SEATING WADS

Wadding in a shotshell has three functions: (1) It compresses and holds the powder so it will burn properly. (2) It acts as a gas seal. (3) It cushions and protects the shot charge.

In past years various wadding materials such as felt, cork and paper were extensively used. Today, plastic materials have all but replaced the old type wads (see "Shotshell Wads" chapter page 185).

5. CHARGING SHOT

As with the powder charging step, most present day machines have a built-in shot measure. The measure is designed to drop a fixed charge of shot into the case. A shot bushing which is inserted into the measure, controls the amount of shot it throws.

6. CRIMP STARTING

The plastic used in today's shotshells is a tough material. It will not bend into a crimp form as readily as the paper cases. Therefore, it is necessary to complete the crimp in two stages. This, the first stage, is called crimp starting. Crimp starting consists of the use of a forming die which starts the folds, or pleats, in the mouth of the case.

7. CRIMPING

This is the second and final stage of crimping. A forming die closes the case into the familiar pie shaped design. This type of closure is called a fold crimp.

8. RESIZING

When a shotshell is fired the walls of the case swell to the chamber size of the gun. These same walls will bulge even more as the shotshell case is subjected to the various reloading operations of wadding, crimping, etc. To correct this condition and to make sure that the finished round will chamber freely, resizing is necessary.

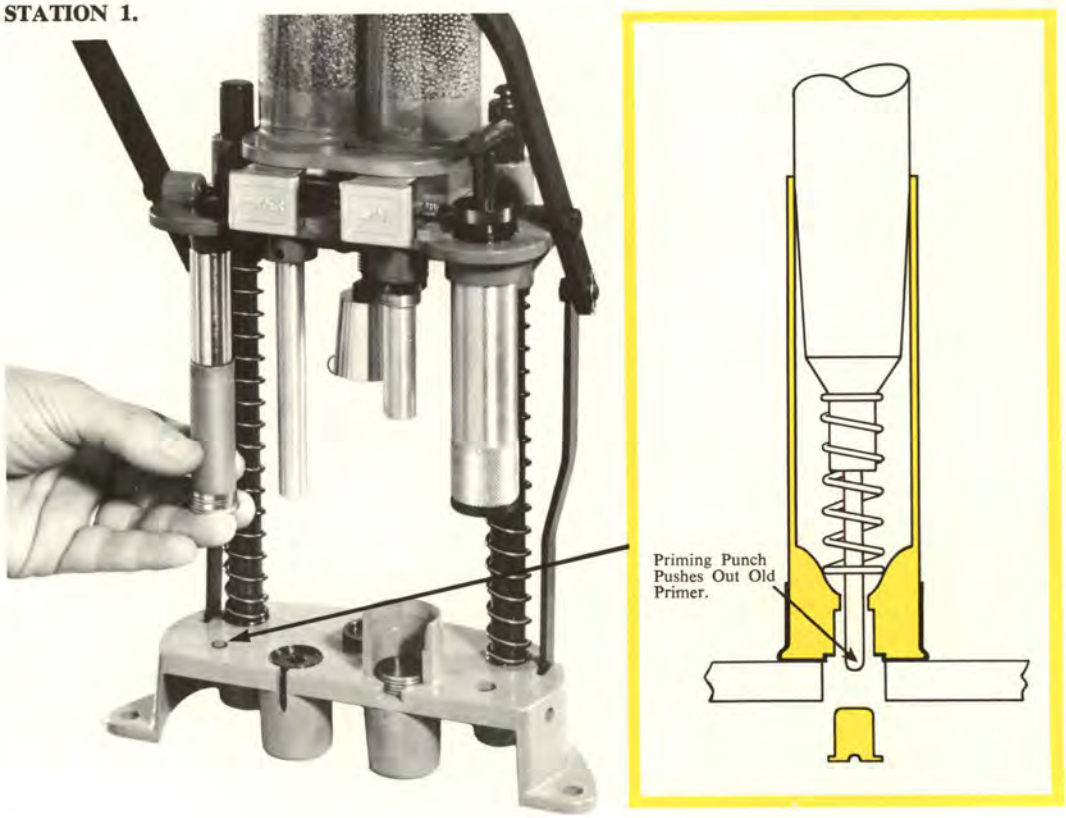
As you read through this chapter, you will note that two reloading operations are sometimes completed in but a single step.

LET'S GET STARTED

The shotshell reloader pictured on the following pages contain five loading stations. The text accompanying each illustration explains the operations that are required at each station.

Until you have become familiar with the functions of each station, do not try to obtain speed. Loading speed will come naturally as you develop a rhythm in your movements. Perform the operations slowly and strive always for a consistent uniformity of motion. Now, if all your components have been checked out, let's fill up the powder and shot hoppers and commence loading.

STATION 1.



STATION 1. (Decapping)

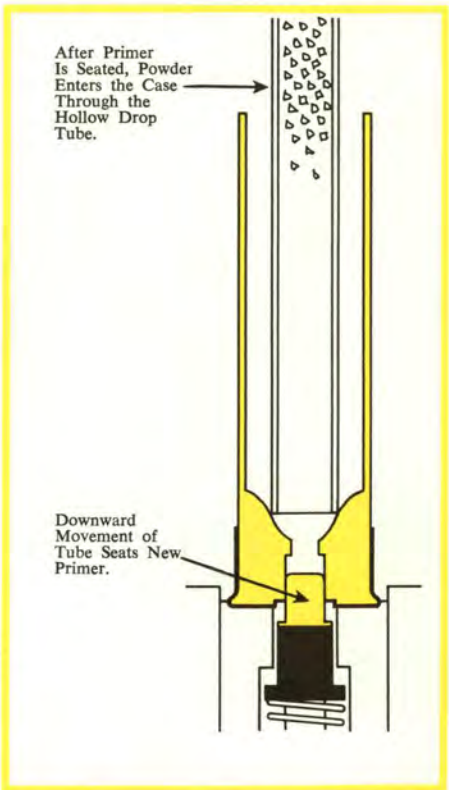
Select a fired shotshell casing and slip it up over the decapping punch as shown in the illustration. Hold the casing in this position with your hand as you pull the press handle all the way down. The punch will carry the casing down with it and expel the spent primer from under the press. Raise the handle and remove the casing. It is ready to be primed and charged.

STATION 2. (Priming and Charging Powder)

A new primer is placed (flange down) into the priming base as shown in the illustration. Place the head of the shotshell in the circular recess over the primer. Pull down lightly on the press handle and you will note that the powder drop tube will enter the case and force the case down over the primer. The downward pressure on the handle should be only hard enough to seat the primer — no more. Now, hold down on the handle while you operate the powder slide. Pull the slide out and push it in smoothly with a single stroke in each direction.

Raise the press handle and remove your shell. It has been primed and charged with powder.

STATION 2.



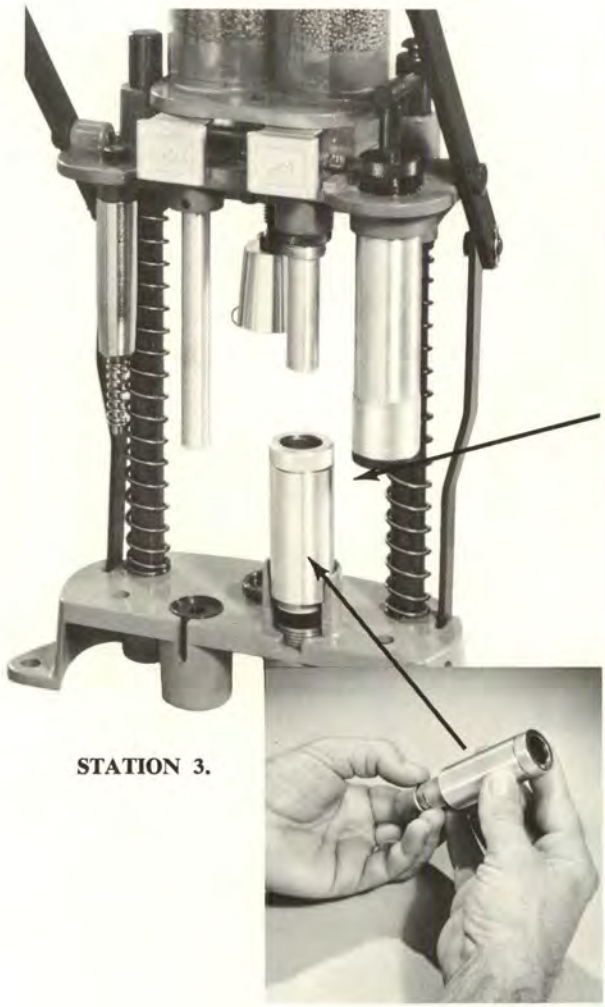
Seat primers so that the flange of the battery cup is firm against the case base. If the primer is loose in the pocket, discard the case.

STATION 3. (Wadding and Charging Shot)

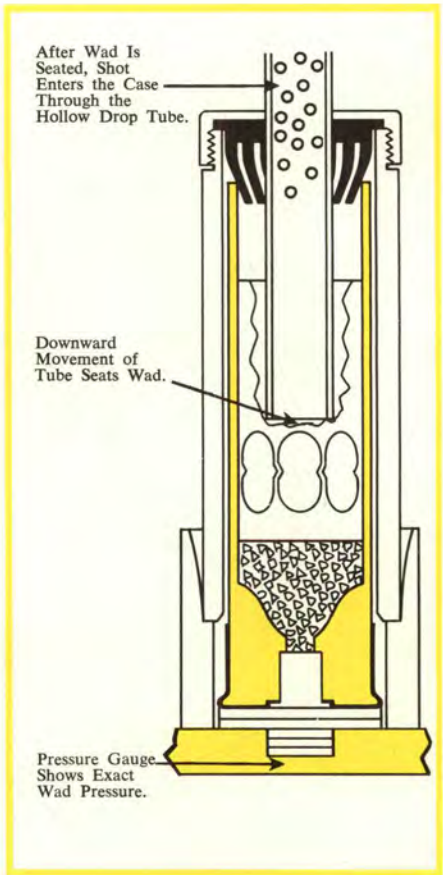
Once the case has been primed and charged with powder it is ready to advance to the third station of the press. Here is where we insert the wads and put in the shot charge. So that the wads will enter the case easily, the case is first inserted into a wad chamber (see illustration). The wad chamber and case are then set into the base collar over the pressure gauge. Wads are started into the chamber by hand.

Pull down on the press handle and the wad will seat firmly against the powder. The pressure gauge will tell you exactly how much pressure you are applying. Now, hold the handle down and operate the shot slide. Pull the slide out and push it in smoothly with a single stroke in each direction.

Raise the handle carefully and remove your case from the wad chamber. It is now ready for crimping.



STATION 3.

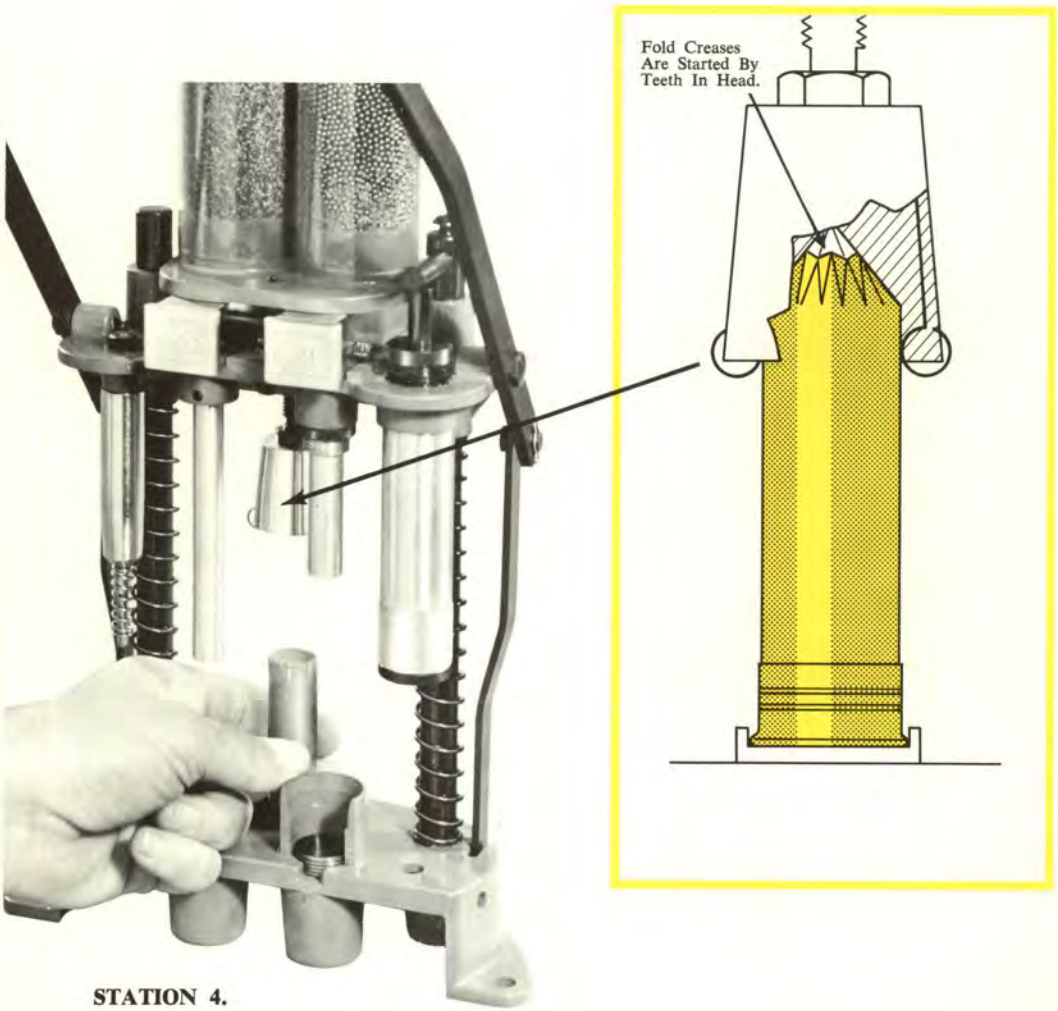


STATION 4. (Starting the Crimp)

The crimp starter is set to the back of the loader as pictured in the illustration. Many plastic cases (and new paper cases) require the use of the crimp starter.

Depending on brand and style, cases vary in the number of folds or pleats which are used to close the crimp. Some cases require eight folds, others six. Be sure that your crimp starter is equipped with the appropriate head for the case you are loading.

To use the crimp starter simply place your charged case in the alignment base under the starter and pull down the handle. The self-aligning arm will pivot the starter head so that it meshes to the existing fold creases in the case mouth (see illustration).

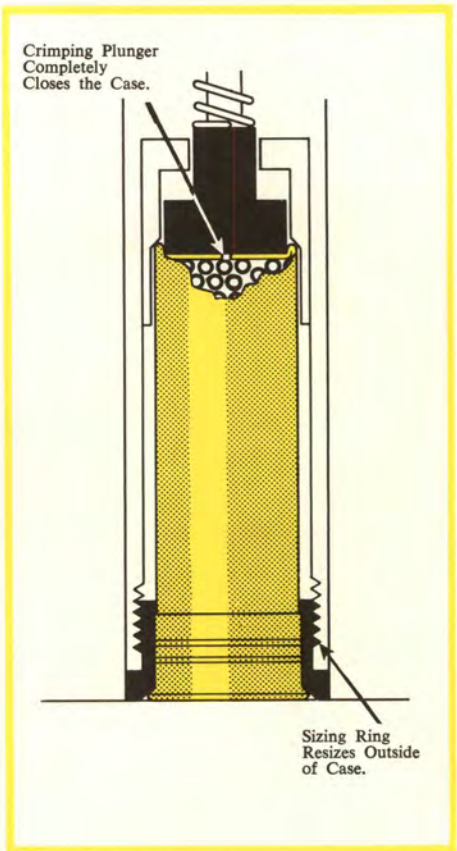


STATION 4.

STATION 5. (Crimping and Sizing)

This is the final operation in loading a shotshell. Here we completely close the mouth with a good firm crimp and resize the case. Slip your shotshell up into the crimping and sizing die as shown in the illustration. Pull the press handle all the way down. Allow the handle to raise slowly. Now, firmly force the press handle up so that the ejector rod (in the top of the die) contacts the ejector stop. This action will automatically free your finished shell from the die.

STATION 5.



SHOTSHELL DATA & PREAMBLE

The loading data contained in this shotshell section of the 44th Handbook supersedes all previous reloading data published in preceding issues of the Lyman Handbook. The data listed in this section has been tested by our technicians and found to be safe when loaded with our components and fired in our test guns under our controlled conditions. Since the Lyman Gun Sight Corporation has no control over the actual loading, choice or condition of the firearms and components used, no responsibility for any use of this data is assumed.

The velocities printed in this section were recorded at a distance of 4½ feet from the muzzle of the test gun. The following is a further explanation of the loads listed.

COMPONENTS — The reader is cautioned against changing, or altering, the listed components. Shotshell ballistics and pressures can change drastically if cases, primers, wads, etc., are altered or substituted for those listed. For further explanation see "Shotshell Ballistics and Tips" following this data section.

WADS — Wads are listed in their loading order. For example, the first wad listed goes on top of the powder charge and the others follow it in their printed order. For further information on the various types of wads and their source of manufacture see the "Shotshell Wads" chapter which follows this data section.

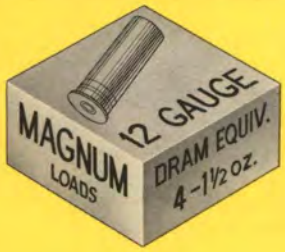
WAD PRESSURE — For the majority of the shotshell loads listed in this Handbook, you will require almost no wad pressure. Use only enough pressure to seat the wads firmly on the powder. In some instances, however, due to variations in shot, or powder density, it may be necessary to increase the wad pressure. If the components will not fit into the case, feel free to add wad pressure (anywhere from one to one hundred pounds) if required. This compresses the wads and leaves room for the rest of the components and crimp.

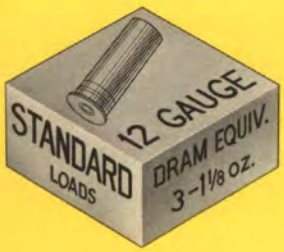
GAUGES AND SHELL LENGTHS — The following gauges and shell lengths are listed in this data.

10 Gauge — 3-1/2″ and 2-7/8″ lengths
12 Gauge — 3″ and 2-3/4″ lengths
16 Gauge — 2-3/4″ length
20 Gauge — 3″ and 2-3/4″ lengths
28 Gauge — 2-3/4″ length
410 Gauge — 3″ and 2-1/2″ lengths

For Information On Selecting A Load, See The Reverse Side Of This Divider . . .

When originally purchased, your shotshells where marked very similar to those pictured below.

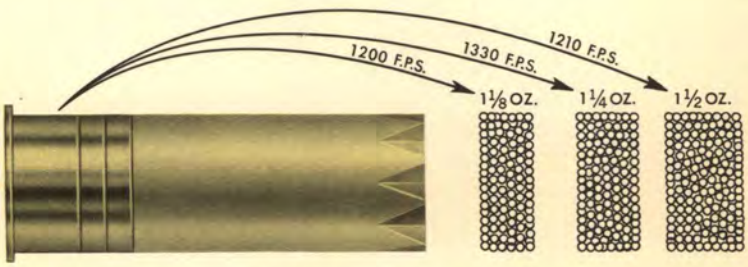




The shotshells were marked with a "Dram Equivalent" and the shot charge weight in ounces. This "Dram Equivalent" does not mean that these shells actually contained this many drams of smokeless powder. They did not and it would be extremely dangerous to reload these shells assuming that this represented the actual weight of the original powder charge.

"Dram Equivalent" is really a rather obsolete term which is used to express the approximate velocity of a shot charge. The term itself is far from exact, but it draws a comparison between the velocity of a shot charge driven by an unknown amount of smokeless powder to that of a similar charge driven by a given number of drams of black powder.

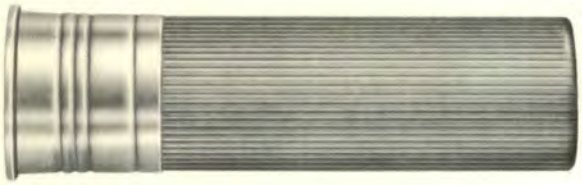
To reload shotshells intelligently, we must think in terms of actual velocity and compare this velocity to the weight of the shot charge.



Many factory loads which are marked as Magnum, while they deliver a heavier shot charge to the target, may actually have a lower velocity than another load which is marked as a normal high velocity load.

The shotshell data in this Handbook is listed by actual (chronographed) velocity not dram equivalent. Loads are shown in order of: GAUGE, SHELL LENGTH, SHOT CHARGE, WEIGHT and VELOCITY. To determine the load which best suits your purpose, first locate your gauge and appropriate shell length. Then select the shot charge weight that you wish to use. By comparing the loads listed you can then choose the velocity level that is required for your shooting.

Note — It should not be assumed that a low velocity necessarily indicates a low chamber pressure. For more information on shotshell reloading see "Shotshell Ballistics and Tips" which follows this data section.



10 GAUGE

SEE SUB HEADINGS FOR SHELL LENGTHS AND SHOT WEIGHTS

With the components available to the reloader it is very difficult to obtain satisfactory results from reloads in this gauge.

After extensive research only a very few loads consistently delivered the uniform ballistics required to meet the exacting standards which we had set for data in this Handbook.

12 GAUGE

SEE SUB HEADINGS FOR SHELL LENGTHS AND SHOT WEIGHTS

This section includes data for all the 2-3/4" and 3" shells which lended themselves readily to reloading.

The Remington/Peters plastic target case gave the best over-all reloading results. This is based on the total number of reloads we could obtain from each case and the number of varying loads which could be put into the case. This case is readily identifiable by its plastic inner base wad and the grooves which appear on the circumference of the brass portion of the case. For complete case description see chapter titled "Shot Shell Ballistics and Tips" which follows this data section.

In Winchester and Western cases we suggest that the over powder wads for all loads be inserted individually and visually checked for proper seating.

The data for the 3" cases with the heavier shot charges is somewhat limited due to the lack of suitable reloading components.

Test Gun 3" Shells — Mossberg 500 — 30" Barrel

16 GAUGE

SEE SUB HEADINGS FOR SHELL LENGTHS AND SHOT WEIGHTS

The data for this section is for 2-3/4" shells only. In some older guns of foreign manufacture, chambers of 2-9/16" were common. It is not safe to use 2-3/4" shells in these chambers. Foreign 2-3/4" chambers are usually marked 70mm whereas 2-9/16" chambers are usually marked 65mm. Where there is doubt have a competent gunsmith measure your chambers.

Test Gun — Mossberg 500 — 28" Barrel

20 GAUGE

SEE SUB HEADINGS FOR SHELL LENGTHS AND SHOT WEIGHTS

The 20 gauge gun is fast gaining in popularity. With the 1 ounce loads it will do anything that the lightest 12 gauge loads will do. If you have a 20 gauge gun chambered for the 3" shell it will enable you to shoot a 1-1/4 ounce load which will equal the standard 12 gauge Hi Velocity loading. Combine this, with the 7/8 ounce loads which are ideal for moderate ranges on small game birds, and you have a very versatile shotgun.

Test Gun — 2-3/4" Shells — Mossberg 500 — 26" Barrel

Test Gun — 3" Shells — Mossberg 500 — 26" Barrel

28 GAUGE

SEE SUB HEADINGS FOR SHELL LENGTHS AND SHOT WEIGHTS

The 28 gauge is an excellent choice for the beginner or recoil shy shooter. Offering slightly better patterns it will give the beginner more confidence than he could obtain using a .410. Some older 28 gauge guns were chambered for 2-1/2" shells. Do not use 2-3/4" shells in any 28 gauge gun unless it is chambered for this length case.

Test Gun — Remington 11-48 — 26" Barrel

28 GAUGE 2¾" FIELD LOADS - 1 oz. SHOT

POWDER	PRIMERS	WADS*	VELOCITY

SHOTSHELL BALLISTICS AND TIPS

It is not surprising that many handloaders, who are knowledgeable about metallic cartridge reloading, scratch their heads in bewilderment when confronted with the task of loading a shotshell. If a handloader tries to assimilate all that he reads about shotshell reloading, he can quite easily become confused.

Little has been written about the loading of today's shotshells which has indeed become a modern science. Let's face it, dad's old paper case has just about departed the scene for good, and along with it bulk shotgun powder and hair wads. They have been replaced by more sophisticated ballistic materials. Shotshells today are far superior to those of the past. Yet many old ideas and assumptions, which no longer apply, are still being taught as ballistic fact to the modern reloader. So, to clear the air, let's forget the past and see what happens when a load is built out of today's components.

CHAMBER PRESSURE

Of course, the amount of safe chamber pressure has not changed. Ten thousand to ten thousand, five hundred pounds P.S.I. still constitutes a safe maximum reload for modern steel (not Damascus) shotgun in good condition. What has changed are the components that are employed to build and to control chamber pressure. As the components become more efficient, they also require more care in the way they are selected and used. Each case brand, each primer, each variation in wad composition and configuration sets up a completely different set of circumstances which must be considered in loading and in its affect on results. In our tests, for instance, changes in components (case brand, wads or primer) have caused pressures to climb from a safe 6,000 pounds P.S.I. to a very questionable 16,000 pounds P.S.I. Unlike fired riflle and pistol cases, shotshell cases do not lend themselves to reliable pressure interpretation. Generally speaking, indications of excessive chamber pressure cannot be detected on the fired shotshell casing until safe pressures have been greatly exceeded.

Developing shotshell reloading data, using todays components, is an exacting technical job. It requires somewhat more elaborate equipment than you are likely to find on the average reloading bench. The day has long since past when it can be safely assumed that any combination of components that seem to "fit" can be assembled into a safe and efficient reload. For example: there are several brands of primers that "fit" the primer pockets of each of dozens of brands and gauges of shells. Relying purely on this "physical fit" could result in a "ballistic misfit" when the ammunition is assembled and fired.

The same can be said of the wad column which is used to fill the space between the powder and shot charge. It must be compatible with the rest of the load. A change of primer or wad column in otherwise identically loaded ammunition almost always requires a change in the powder charge. Not infrequently another powder of different burning characteristics must be used if we alter one of the components and wish to maintain a similar ballistic level.

The Shotshell data in this Handbook lists the cases and exact components used in each load. All loads have been carefully tested by our technicians. The reader is cautioned against altering, or substituting the components shown.

WAD PRESSURE

Considering all aspects of reloading good shotshell ammunition, the question of wad pressure seems to get attention which is all out of proportion to its actual significance. While we cannot speak for the recommendations of others, we can speak for the data contained in this Handbook. How much wad pressure do you need on the wad column? Never very much . . . sometimes none at all. Very simply stated, you need whatever pressure is required to get the wad through the wad guide and down on the powder charge. If there is not room in the case to accommodate the shot charge and crimp then you need slightly more pressure. Add pressure (from one to one hundred pounds) to compress the wads enough so that the shot charge will fit the case, **and no more.** For further information on wads, see "Shotshell Wads" chapter which follows.

POWDER AND SHOT BUSHINGS

All shotshell reloading machines now manufactured, measure powder and shot charges by volume. As shot density may vary greatly from brand to brand, or from one size shot to another, manufacturers must use a "middle of the road" type of tolerance in designing shot bushings for these machines. This tolerance is usually computed using No. 7-1/2 chilled shot. If a shot bushing, which at one time dropped a one and one-eighth ounce charge, suddenly goes crazy and begins to throw a heavier or lighter charge, don't write the manufacturer. The variation is probably in the shot itself.

To a smaller extent, you may also encounter variations in powder density from lot to lot. A new can of powder may have a slightly different density than the last can of this same powder. Considering all variations, however, the human variation in operating the machine is usually the greatest culprit. It is not possible to walk up to a reloading machine and throw a powder or shot charge and obtain an accurate appraisal of what the bushing will throw during the normal loading cycle. Bushing dimensions are very carefully calculated and take into consideration the vibrations and jarring that the machine receives during the complete loading cycle. If you operate the metering bars, without actually loading a shell, your charges will always be light.

After you set up for a load, or change from one brand of shot, or lot of powder, take the precaution of weighing both your powder and shot charge on an accurate scale. Remember, you must actually go through the loading operation to obtain an accurate reading of what the bushing will throw. If the variation in either powder or shot is no more than five percent, continue to load using the metering bars on the machine.

If you encounter a greater variation, we recommend that you weigh all of your charges (both powder and shot) on a reloading scale until you have corrected the problem.

DRAM EQUIVALENT

No one can explore the mysteries of shotshell reloading without uncovering the biggest imponderable of all, "Dram Equivalent". This term has been around for years, but it can be very misleading.

Shooters themselves have misconstrued the meaning of the term "dram equivalent" in various ways. Some shooters honestly believe that dram equivalent represents the actual powder charge. Of course, it does not. Some read chamber pressure into this time worn term. Actually, dram equivalents and chamber pressures are totally unrelated. What it really means is that these shells are loaded with sufficient smokeless powder to drive the shot charge at a **velocity** which is **equivalent** to the velocity of a similar charge driven by a given number of drams of black powder. Confusing? You bet it is!

The following is a list of dram equivalents and the approximate velocities which they represent. Note that all of the dram equivalents are the same, although the velocities are different according to gauge and shot weight.

	Equiv.			
12 GAUGE	3 drams	1 oz.	#7½	(approx. vel. 1235 F.P.S.)
	3 drams	1-1/8 oz.	#7½	(approx. vel. 1200 F.P.S.)
	3 drams	1-1/4 oz.	#7½	(approx. vel. 1165 F.P.S.)
16 GAUGE	3 drams	1 oz.	#7½	(approx. vel. 1275 F.P.S.)
	3 drams	1-1/8 oz.	#7½	(approx. vel. 1240 F.P.S.)
	3 drams	1-1/4 oz.	#7½	(approx. vel. 1205 F.P.S.)
20 GAUGE	3 drams	7/8 oz.	#7½	(approx. vel. 1320 F.P.S.)
	3 drams	1 oz.	#7½	(approx. vel. 1275 F.P.S.)
28 GAUGE	3 drams	3/4 oz.	#7½	(approx. vel. 1565 F.P.S.)
	3 drams	1 oz.	#7½	(approx. vel. 1475 F.P.S.)

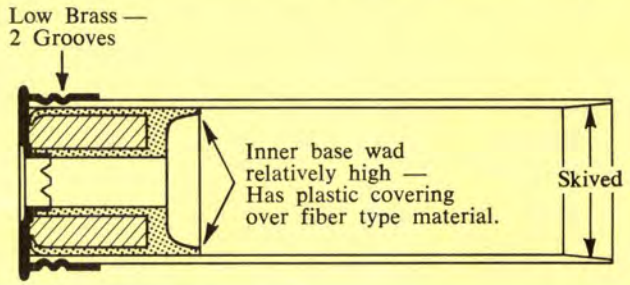
The loads shown in this Handbook are not listed by a dram equivalent. They are listed instead by their actual chronographed velocity.

IDENTIFYING YOUR FIRED CASE

When following the shotshell data as it is laid out in this Handbook, it will be necessary to identify your fired casing exactly and then use this casing only where it is recommended. Six brands of shell casings are covered. These are REMINGTON, PETERS, WINCHESTER, WESTERN, FEDERAL and ALCAN. Identifying Federal or Alcan cases should not be difficult because these cases are marked with names like "Trap Max" etc. which are printed with our loading data wherever they appear.

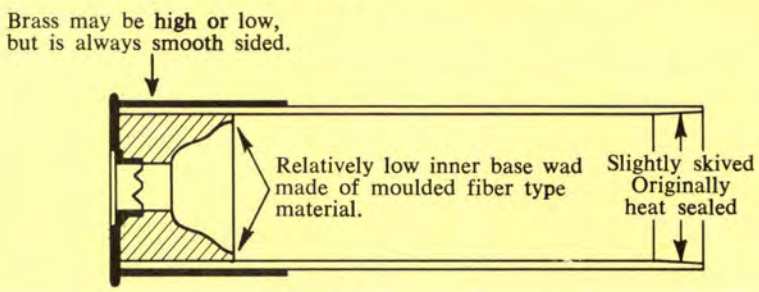
Remington/Peters and Winchester/Western cases may cause some confusion. In order to make their identification easier, we offer the following text and illustrations. The cases listed were chosen for their reloadability. For example, if a particular type case burned through on the first or second firing, we did not feel that it had a suitable reloading life, and therefore did not include it. The Remington/Peters and Winchester/Western cases are as follows:

REMINGTON & PETERS PLASTIC TARGET CASES 12 OR 20 GA.



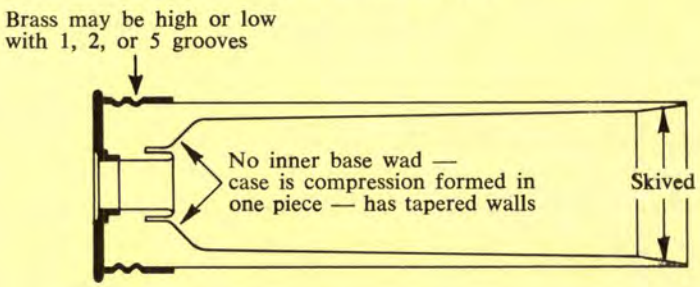
Target cases (originally loaded for trap and skeet) in either Remington or Peters brand have the same inner construction as pictured above. These cases have a solid plastic inner base wad in 20 gauge and a moulded fiber wad with plastic covering in 12 gauge. They have low outside brass with two grooves and are manufactured in 12 and 20 gauge only.

REMINGTON & PETERS PLASTIC S.P. CASES
10, 12, 16, 20, 28 or 410 GA.



Field and Express load (steel/plastic) cases in either Remington or Peters brand have the same inner construction as pictured above. These cases have a moulded fiber inner base wad and a steel head which is brass coated. Regardless of whether the case has high or low outside brass, it may be used with this group. This type of casing is manufactured in 10, 12, 16, 20, 28 and 410 gauge. Original buckshot or slug cases have no skiving at the mouth and are not recommended for fold crimp loads.

WINCHESTER & WESTERN COMPRESSION FORMED PLASTIC CASES:
12, 16 and some 20 GA.



This group includes all 12 gauge AA target, Super Speed and Super X cases, plus 16 gauge Super Speed and Super X cases. 20 gauge AA target cases are also included. (20 gauge Super Speed and Super X cases, while they are compression formed, are not included for they vary slightly in volume from the 20 Ga. AA case).

CASE LIFE

Aside from its ability to deliver a good pattern at a respectable velocity and range, the next kindest thing we can say about a particular reload is that it is easy on the case. Case life is important, for cases cost money and saving them as much as possible is the object of the game.

With the cases and loads listed in this Handbook, you may expect a reasonably long case life. Depending upon the load you choose, five to fifteen loadings per case is a pretty close estimate. The longest case life will be experienced with those loads which make use of a shot sleeve. Besides improving patterns, shot sleeves also prolong case life by protecting the mouth of the case from the wearing effects of the shot charge.

However, repeated firing and reloading will eventually wear out the cases. Correct reloading requires the inspection of each case before reloading it — discarding those that show defects.

When inspecting cases, look for the following defects and discard any cases on which they appear:

BASE WAD Check the case to insure that inner base wad is still intact and that parts of it have not blown away. A good procedure is to use a wood dowel as a depth gauge as explained in a previous section, "Loading Shotshells."

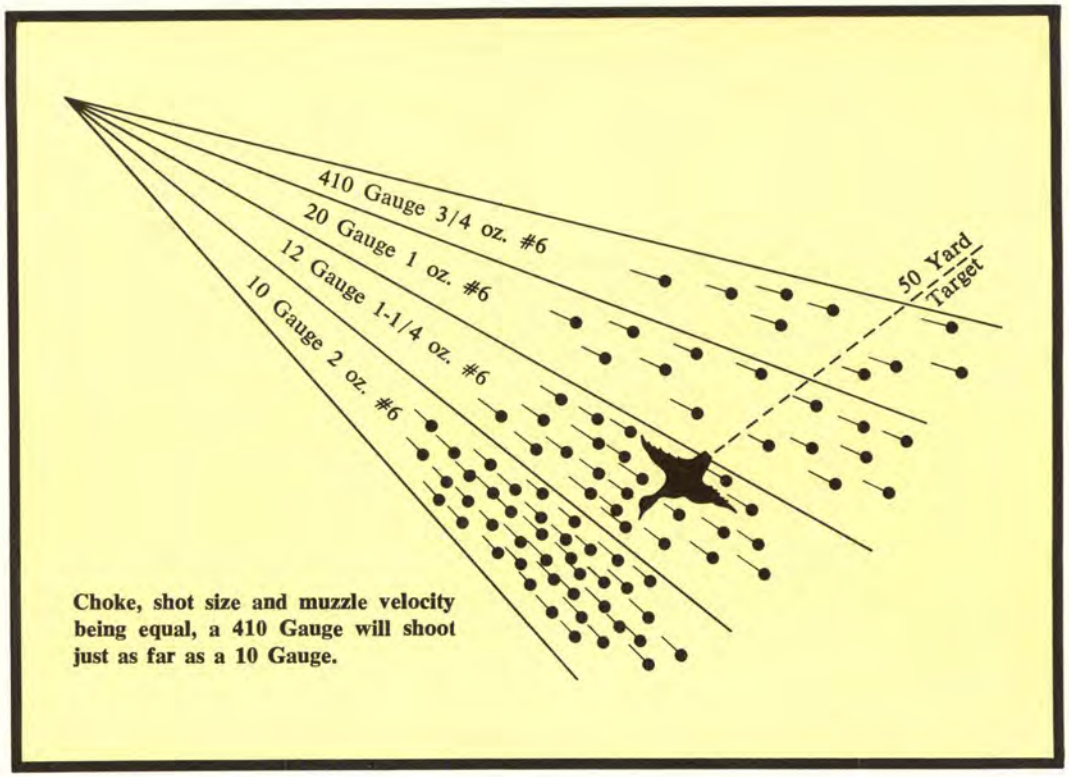
PRIMER Check for loose primers when loading and for evidence of gas leakage around a fired primer. This is an indication that the primer pocket has stretched due to fatigue.

CASE WALLS Check the case walls for pin hole burns. Also, twist the case head slightly with your fingers to see if it has loosened from the case body.

CASE MOUTH Discard cases that have torn or blown-away mouths. These cases will not crimp properly.

PATTERN

Some shooters hold the opinion that a large gauge shotgun will shoot further than a smaller gauge. This isn't so. Choke, shot size and muzzle velocity being equal, the shot charge from a 410 will travel equally as far as the shot charge from a 10 gauge. The big difference is in the density of their patterns. Bigger gauges throw (or are capable of throwing) more shot. This makes them more effective at a long range. A good full choke 10 gauge, for instance, will place more shot in a 30″ circle at 50 yards than we could possibly load into a 410 cartridge.

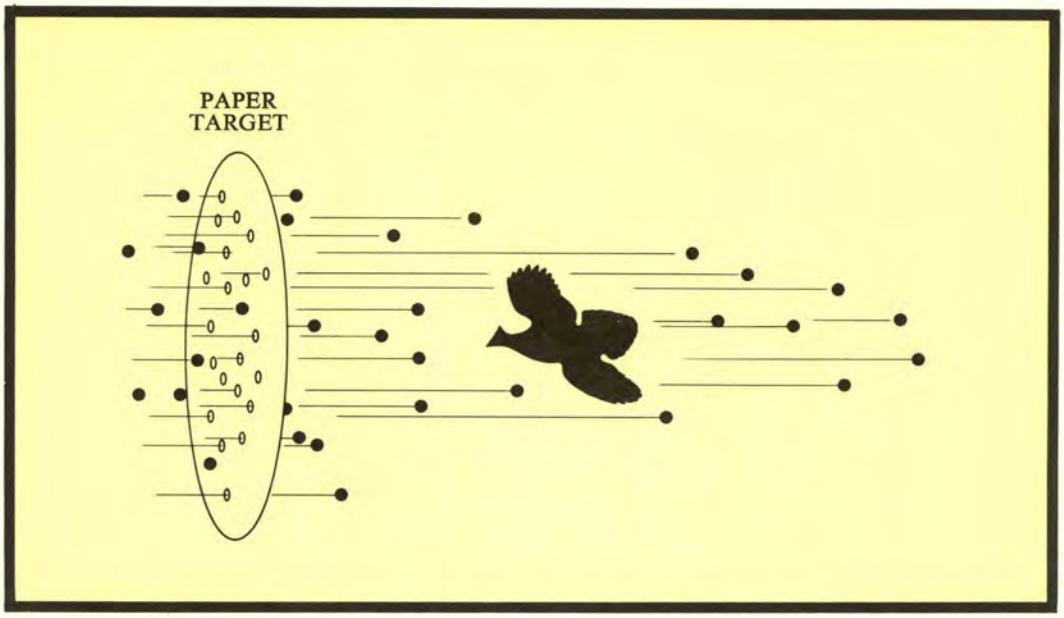


Choke, shot size and muzzle velocity being equal, a 410 Gauge will shoot just as far as a 10 Gauge.

While our 50-yard target shown above flies right through the lighter patterns without being hit, he runs into greater difficulty as more and more shot gets into his flight path. Were he to receive a hit by one or two pellets from the smaller gauges, they would strike with the same force and do as much damage as an equal number of pellets from the 12 or the 10 gauge.

Patterning our shotgun on paper is important for two reasons. One, it provides a method for selecting the best choke and shot size for a particular range and target. Two, it gives us a mental picture of the ability of our shotgun at each specific range. The second reason is the more important because it teaches us that there is a time to shoot and a time not to shoot. We learn to time our shot and to take it where range and pattern are most effective.

To pattern your shotgun, secure several large sheets of brown wrapping paper. Draw a 30″ circle on each piece and make a mark, clearly visible, indicating its center. As you will be shooting at the paper, it will be necessary to secure it in a target position. Place your paper target down range at a distance that is average for the majority of your shooting. For example, if your average shot is between 30 to 40 yards, place your patterning target 35 yards from the muzzle. Fire your shotgun at the center mark on the target. Check your pattern and concern yourself only with those pellets that strike inside the 30″ circle. Bear in mind that the density of your pattern must be such as to not allow a flying target to slip through it.



Remember, your shot reaches the target in a somewhat strung out fashion (shot string). The pattern picture that you see on your paper target is not completely accurate. Unless the circle is well covered, a fast-flying bird could slip through.

Pattern density may be adjusted in a variety of ways. One, use another shotgun of a larger or smaller gauge. Two, change the choke of your present gun to a tighter or more open boring. Three, select a load that contains a heavier or lighter shot charge. Four, vary the density even further by experimenting with different shot sizes.

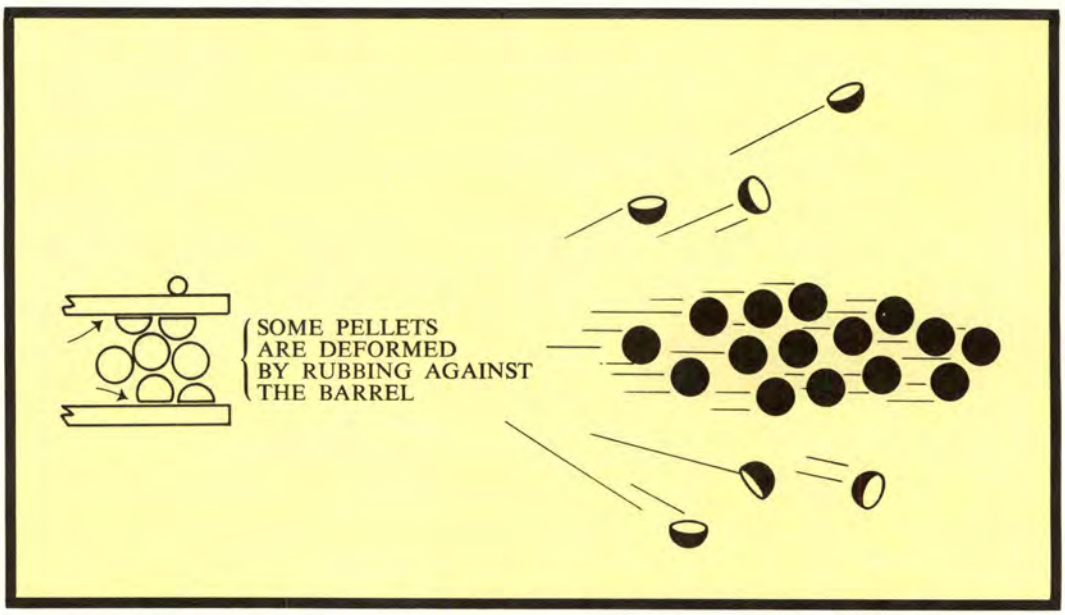
The chart below shows the number of pellets that are contained in a one ounce shot charge. Note, for example, how we can almost double the number of pellets in our charge if we change from 6's to 8's.

SHOT SIZES

No.	9	8	7½	6	5	4	2
Diameter in inches	.08	.09	.095	.11	.12	.13	.15
Approx. pellets in 1 oz.	585	410	350	225	170	135	90

Some pellets loaded into our shot cartridge will either not reach the target at all, or they will arrive at the target in a deformed state. These are the pellets which, due to the friction of rubbing against the barrel, are no longer round in shape. As these pellets lose velocity rapidly and do not fly true, they are lost from the effective shot charge. Naturally, the more deformed the shot, the worse the pattern.

Some gauges, due to the shape of their shot column, will deform more shot than others. The 410, for instance, is a notorious shot destroyer, as its long slender shot column forces a large percentage of its charge against the barrel. This, coupled with its light 3/4 ounce charge has an adverse effect on its patterns. Using a smaller size shot would help this condition in the 410. In other gauges, the deformation of shot can be almost totally eliminated by using the shot sleeves that are popular today. These sleeves offer a tremendous advantage in obtaining better patterns.



Part of the shot charge is deformed by friction. These pellets are usually lost from the pattern.

SHOTSHELL WADS

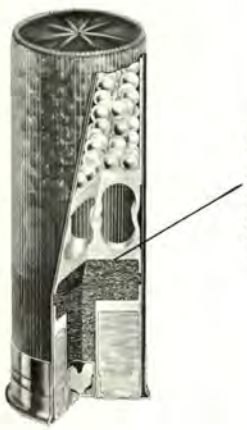
To achieve the proper ballistics for a finished shotshell, the correct selection of a wad is vitally important. Indiscriminate use of wads can result in bloppers, muzzle flashes, excessive breech pressures and erratic velocities. Under no circumstances should wad columns be altered.

Wads should be seated individually. Use just enough wad pressure to seat the over powder wad firmly on the powder. Each successive wad should be seated with only enough pressure to insure its bottoming on the previous wad. The amount of pressure required varies with the type of wad and the type of case used. A case with a tapered wall requires the application of a greater than normal amount of wad pressure. This may vary from 1 to 40 or 50 lbs.

A good practice is to make up a sample round. Load your powder and seat the wads with what you feel is the minimum pressure requirement. Then, before loading the shot, cut down one side of the case with a knife. Visually inspect the wads to determine whether they have properly bottomed. Be sure no air space is present between powder and the over powder wad, or between the individual wads. If any such spaces exist, more wad pressure is needed.

If you find that due to difference in shot diameter, or density, you have insufficient room for a good crimp, apply additional wad pressure to the top of the wad column. This will compress the wads somewhat and allow more room for the shot charge and crimp. Use only as much pressure as is necessary to insure a good crimp. Changes in shot size often require a change in wad pressure. A 1-1/4 ounce charge of #4 shot will require more room than an equal weight of #9 shot.

The use of a wad column which has a sleeve around the shot column is desirable. These sleeves prevent the shot from becoming deformed in its passage through the bore, thus improving patterns. Of course, leading is completely avoided with such wads. But their greatest advantage, is extended case life. The abrasive action of the shot on the case mouth is eliminated and we can, in many instances, double the case life over that of a non-sleeved shot charge. Of course, the one-piece wads which combine a shot sleeve are the ultimate in convenience and long case life.



The following wad listing does not by any means include all of the wads available to the handloader. It does, however, cover all the wads used in the data contained in this Handbook. It is offered as a guide to help you to recognize the various types of wads and to understand their proper usage.

REMINGTON WADS

Card Wads

Card Wads. These cardboard wads in .135″ size were used in all gauges from 10 to 410. The .200″ size was used in 12 and 16 gauge. These are basically over powder wads. However, their use is extended to a general filler wad also. Normally packed 1,000 to a box.

"H" Wads

"H" Wads. These gas sealing, polyethylene wads are very efficient over powder wads. They were used in 12, 16 and 20 gauges. Normally packed 250 to a box.

Felt Wads

Felt Wads. These wads were used in all gauges from 10 to 410. While designed primarily as a filler wad, they are in some instances used directly over the powder. Sizes used included 1/8″, 3/16″, 1/4″, 5/16″, 3/8″, and 7/16″. Referred to as Premium Felt by Remington, they are normally packed 500 to a box.

"Mould-Tite" Wads

"Mould-Tite" Wads. Available only in 12 gauge. The 1/4″, 3/8″ and 1/2″ sizes are used exclusively as filler wads. Lubricated, they are normally packed 500 to a box.

"Power Pistons"

"Power Pistons". These one-piece plastic wad columns are very efficient. They increase case life over conventional type wadding by preventing the abrasive shot from deteriorating the case mouth. This is accomplished by a protective shot sleeve. Several styles were used in the 12 gauge (#W23694, a white colored wad and #W23676, a green colored wad). The 20 gauge wad (#W23678) used and the 28 gauge wad (#W23680) used, were both white colored. Normally packed 1,000 to a box.

REMINGTON WADS (Continued)

"Post Wad"

"Post Wad". This green plastic wad is available only in 12 gauge. It is similar to the power pistons with the exception of a post which fills the center of the shot container. The purpose of this post is to help open up patterns in full choked guns. These wads were designed for 16 yard trap shooters. Remington code number for this wad is #W23618 and they are normally packed 1,000 to a box.

ALCAN WADS

"Nitro" Card Wads

"Nitro" Card Wads. Wads in the .070″ and .135″ sizes were used in 20 gauge. They are basically an over powder wad, but their usefulness is sometimes extended to that of a general filler wad. Normally packed 1,000 to a box.

Air-Wedge Wads

Air-Wedge Wads. Available only in 12 gauge and used exclusively as an over powder wad. They have a very definite top and bottom. The bottom (which goes against the powder charge) is the side on which no ribs can be seen.

PGS Wads

PGS Wads. Plastic gas sealing wads used solely as an over powder wad. Has a very definite top and bottom (cup side against the powder). Used in 10, 12, and 20 gauges.

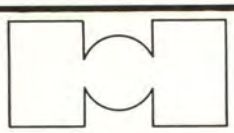
"Flite-Max" Wads

"Flite-Max" Wads. Combination plastic and fiber wads available in 12 gauge only. They offer the advantage of a shot sleeve. Size numbers 1, 4, and 5 were used. Normally packed 250 to a box.

ALCAN WADS (Continued)

"Feltan-Bluestreak" Wads

"Feltan-Bluestreak" Wads. Filler wads used in 10, 12, and 20 gauges. The 1/4″ and 3/8″ sizes were used in all three noted gauges. The 5/16″ and 1/2″ sizes were used in 12 gauge only.



Kwik-Sert Wads

Kwik-Sert Wads. Polyethylene shot strips designed as a shot sleeve for use with conventional wadding. Used in both 12 and 20 gauges.

WINCHESTER WADS

Card Wads

Card Wads. Cardboard wads designed primarily as an over powder wad although in some instances they are used as a filler wad. The .080″ and .135″ sizes were used in 20 gauge. The .200″ size was used in 12 gauge. Normally packed 1,000 to a box.

Plastic Cup Wads

Plastic Cup Wads. Over powder wads available only in 12 gauge. The cup side should be placed towards the powder. They must be seated individually and visually inspected to insure that they have seated without twisting or distorting.

Molded Fiber Wads

Molded Fiber Wads. Edge lubricated wads used exclusively as a filler wad in 12, 16 and 20 gauges. Sizes used included 1/4″, 3/8″, and 1/2″. Normally packed 500 to a box.

WINCHESTER WADS (Continued)

"AA" Wads

"AA" Wads. Double plastic wads used in 12 and 20 gauge. They offer the advantages of a one-piece wad column and extended case life. Numbers WAA12 (12 Ga.) and WAA20 (20 Ga.) are white in color, while the WAA12R (12 Ga.) are red in color. Normally packed 250 to a bag.

FEDERAL WADS

Card Wads

Card Wads. The .135″ size was used in 12 gauge as an over powder wad. Normally packed 100 to a carton.

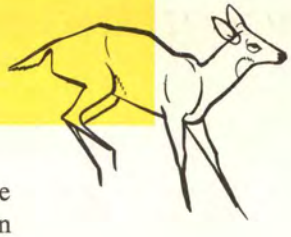
Fiber Wads

Fiber Wads. The 3/8″ and 1/2″ sizes were used as filler wads in 12 gauges. The 1/4″ size was used as a filler wad in both 12 and 16 gauges.

Champion Pellet

Champion Pellet Protector Wads. Plastic one-piece wad columns in 7/8″ size used in 12 gauge only. They offer the advantage of extended case life.

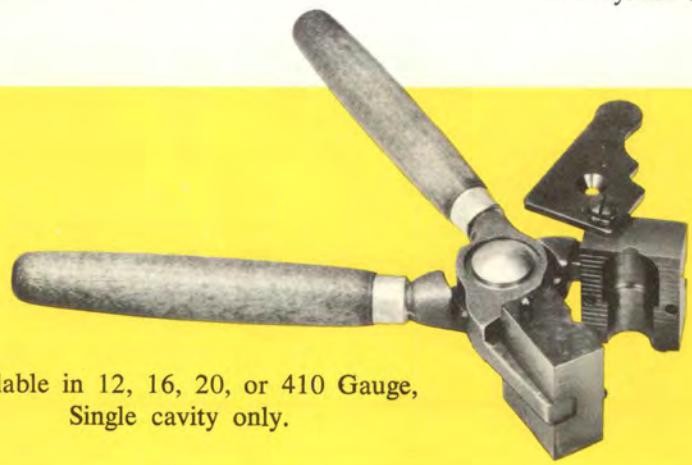
SHOTGUN SLUGS



MUST THEY BE RIFLED?

For many years it was believed that the rifling grooves cut in the body of a shotgun slug helped to stabilize the projectile and improve accuracy. More recent test results indicate that slugs are not rotated by these rifling grooves, but rather travel in the same manner as a dart, or shuttle-cock. They remain head on only because the greater weight mass is in the front of the projectile.

Lyman slug moulds are available for 12, 16, 20 or 410 gauge slugs. These moulds cast perfect hollow-base slugs. Cast slugs do not require rifling and are recommended to be shot as cast. See Lyman catalog for full particulars.



Available in 12, 16, 20, or 410 Gauge, Single cavity only.

BUCKSHOT MOULD

Lyman round ball moulds are available in diameters which correspond to standard factory buckshot sizes. The listing on the right shows the diameter mould required to cast the various sizes of buckshot.

Shot Size	Mould Dia.	Approx. Weight
000 Buck	.360	72 grs.
00 Buck	.330	54 grs.
0 Buck	.319	47 grs.
#1 Buck	.300	40 grs.
#3 Buck	.244	23 grs.
#4 Buck	.235	20 grs.

Loading the Muzzle Loader

This chapter of the Handbook concerns itself with the use of modern replica firearms. The rifles, pistols and shotguns illustrated herein are currently available. They represent a few of the most popular models. For more information about them write directly to the manufacturers listed on the reverse side of this divider.

Only a few years ago it was difficult to locate a shootable muzzle loader. If you did manage to dig one up, it brought top collectors' prices. And why not? Old guns like old furniture, old cars, or old anything have become rare collectors' items. From a shooting standpoint, these old museum pieces were a luxury to own and it was not too practical to put them back into harness. The parts had become brittle with age and broke easily. If you broke a hammer or lock spring, you destroyed much of the gun's value.

When we talk of shooting a muzzle loader today, we are not necessarily referring to the antiques of yesteryear. Many fine guns, exact reproductions of famous old models, are now being made. As these replicas are readily available at reasonable cost, a whole new world of muzzle loading enjoyment has been opened up to us. Today you can buy a brand new muzzle loading rifle, pistol or shotgun from any one of several manufacturers.

This chapter of the Handbook concerns itself with the use of modern replica firearms. The rifles, pistols and shotguns illustrated herein are currently available. They represent a few of the most popular models. For more information about them write directly to the makers listed below. They will be happy to supply literature.

THINGS YOU SHOULD KNOW ABOUT BLACK POWDER

Black powder is the only powder that should ever be used in a muzzle loading firearm. Even today's replicas with their modern steel barrels are not designed for the high pressures of smokeless powders. However, black powder, if improperly handled, can be dangerous. So take care. Further information can be found in the Powder Chapter of this Handbook.

For small arms use — rifle, pistol, shotgun — four specific types of black powder are available. The differences between them are in the size of the grains (granulations). The smaller the granulation, the faster the powder burns. In general, the burning rate of the powder determines its use. A system of marking — a series of the letter "F" — has been used for many years to identify the granulation size of various powders. For example, FFFFG is made with the smallest granulation and it is, therefore, the fastest burning of all black powders. FFFFG is used for priming flint locks which require an extremely fast burning powder.

The following chart is offered as a rule of thumb to help you understand better the various uses of black powder. Do not feel that you must adhere exactly to the chart. It is intended simply as a guide to show approximate applications.

FFFFG	—	For priming flint locks.
FFFG	—	For rifles up to and including 40 caliber. Also for most single shot pistols and all percussion revolvers.
FFG	—	For rifles over 40 caliber and up to 58 caliber. Also for large caliber, single shot pistols and most shotguns.
FG	—	For rifles over 58 caliber and large bore shotguns.

Further on in this chapter we have listed the recommended loads for each of the replica arms covered. For these loads we chose the type of powder which gave us the best results. In general, round balls require more poowder to drive them than do conical bullets. An old rule of thumb for round ball rifles is to use a powder charge equivalent to one-third of the ball weight. A rifle (not shotgun or pistol) is loaded until it makes a sharp "crack" sound when fired. The cracking noise is an indication that the proper velocity has been reached. Some shooters have a tendency to overload a muzzle loading rifle. Don't. There is nothing to be gained by using too much powder. Whatever powder is not burned in the barrel will be blown out the muzzle. To find out quickly whether you are using too much powder, fire the rifle from a prone position with several sheets of newspaper spread on the ground in front of the muzzle. If telltale signs of unburned powder appear on the paper, reduce your charge.

THINGS TO KNOW ABOUT PATCH AND BALL FIT

Muzzle loading guns have a way of being cantankerous when it comes to ball and patch fit. They require a few kind words and a little coaxing before they begin to live up to

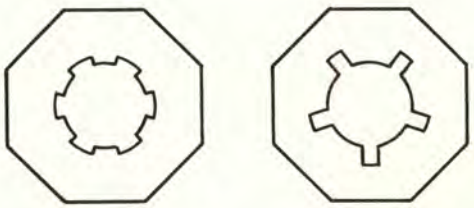
granddad's stories. In order to spare you the guess work and cussing that's required to put a load together, we have tested and listed suggested loads for each of the replica guns shown. These charges, ball diameters and patch thicknesses were found to be accurate in our tests. A newcomer to the sport, however, still requires a knowledge of why a patch is used in a muzzle loading gun and why it is important that this patch fits tightly.

Accuracy with a muzzle loader is based on a paradox: an undersized ball is spun by rifling that it never touches! The secret, of course, lies in the cloth patch. It transfers to the ball the grip and spin of the rifling. It also fills the grooves and acts as a gas check by sealing off the hot gases. Theoretically, any closely woven, tough material that will stand the abuse of being shot out of a rifle is satisfactory for patching. The thickness of this material is something else again. It must be matched carefully to the diameter of the ball.

The thickness of the patch relates directly to the depth of the rifling. The size of the ball, on the other hand, is related to the bore diameter of the rifle. A combination of both of these factors must be carefully considered and regulated for optimum efficiency. As the patch thickness is increased, the ball diameter must be decreased to compensate for the added material between the ball and the lands.

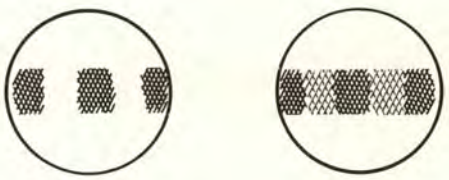
To perform its duties as a gas seal the patch must completely fill the grooves of the rifle. In other words, it must be under considerable compression not only where it contacts the lands, but also at the bottom of each groove. A good deal of cloth must be packed into each groove. Naturally, this can't be carried to an extreme, or a sledge hammer would be needed to load the rifle.

These drawings represent two types of rifling. Although both examples have the same bore diameter, they do not use the same ball and patch combination. The one on the right requires a much thicker patch to fill the deep grooves. Therefore, a smaller ball must also be used to compensate for the tighter fit at the lands.

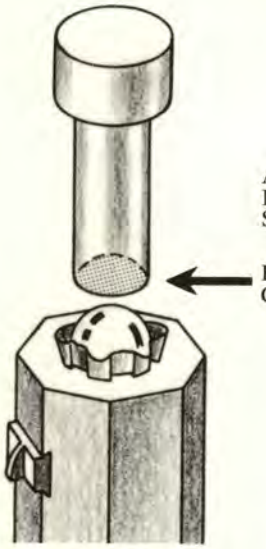


shallow groves deep grooves

When a correctly patched roundball is driven through a barrel, it will show cloth marks completely around its circumference, like the ball on the right. These marks will be light where the ball and patch touched the grooves and heavy where they touched the lands.



incorrect correct



Although a tight fitting combination of patch and ball is the secret to accuracy with a muzzle loader, some compromise must be reached between loadability and complete bore sealing. You must be able to start the ball into the muzzle and seat it on the powder without excessive battering or flattening of the projectile. To shoot well the front of the ball must remain round. The proper loading implements are important here and a Short Starter, as shown in the illustration, can be made easily from a piece of hard wood. The end of the starter should be hollowed out to fit the contour of the ball. One sharp blow on the starter with your hand, or sometimes a mallet starts the ball.

Recovering fired patches gives you a good clue as to the effectiveness of your patching material. They will usually be found five to ten yards in front of the muzzle. The following illustration tells you how to read patch signs.

___ POOR Patch much too thin to seal the bore. Center is burned out by gas blow-by.

___ POOR Patch too thin to seal the bore. Overall blackening still indicates gas blow-by.

___ GOOD Patch fits tightly and seals well. Blackened cross mark indicates effective sealing off of gas.

THINGS TO KNOW ABOUT BULLET MOULDS

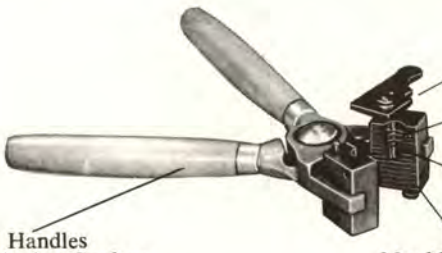
Some of the earliest American bullet moulds were made rather crudely of soap stone, with a cavity worked into them by hand. Later on, somewhat superior moulds were made of iron or bronze. Even these, however, lacked certain refinements essential to good bullet casting. One of the notable deficiencies in the old moulds was that the handles were not sheathed in wood. Consequently, after casting a few bullets, the operator needed asbestos covered hands. Many early moulds didn't even have a sprue cutter so the rifleman had to cut off the sprue with his hunting knife. This, of course, made consistency difficult, and accuracy suffered accordingly.

The chief deficiency in antique mould design is the lack of provision for bleeding off the air that becomes trapped in the mould. Because the air cannot escape, it forms a bubble, or air pocket, within the bullet. Such bullets may appear perfectly normal on the surface,

but they are too unbalanced, ballistically, to group accurately. Air pockets can be detected by weighing the bullets on a conventional reloading scale. Those that do not come up to a consistent weight can then be melted down and recast.

Suggested Lyman mould sizes (for the replica guns illustrated) are listed later on in this chapter. These moulds offer all the modern features required for casting truly good bullets and round balls. For more information on bullet moulds and casting techniques, see "Accuracy with Cast Bullets" in the Reference Section of this Handbook.

LYMAN MOULDS ARE AVAILABLE FOR 75 DIFFERENT ROUND BALL DIAMETERS AND 800 DIFFERENT BULLET STYLES AND WEIGHTS



CLEANING YOUR MUZZLE LOADER

As black powder is highly corrosive, your gun must be carefully cleaned each time it is used. The best solvent for black powder residue is still hot soapy water. It is important that the water be boiling hot. This not only does a better job of removing powder fouling, it also heats up the barrel metal. A hot barrel will dry itself off rapidly without rusting. Use a bar type soap (not detergent) and cut up small chips of soap, stirring them into the water.

If the gun is a break down type, like the revolver or shotgun, disassemble the piece and scrub the barrel well. Also the cylinder if it is a revolver. A good way to clean barrels of the shotgun type is to submerge the breech end in the water and pump the cleaning rod up and down in the barrel. This will draw the water in and flush it out through the nipple holes. When the barrels are clean, set them aside and allow the heat in the metal to dry itself off. Fouling on the metal parts of the action should be wiped clean with an oily cloth. When the barrel drys, oil it well (inside and out) and reassemble the gun.

Some guns such as the Kentucky rifle, should not be disassembled for cleaning. As their barrels are held on by wood screws and pins, constant disassembling would soon destroy them. The method generally used for cleaning guns of this type is to close the hammer on a piece of cloth, fill the barrel half-full of hot soapy water, cork up the muzzle and shake the rifle up and down. Now, cock the hammer and hold the rifle with the nipple toward the ground. As you run the patch down the barrel, the water will pump out through the nipple. Repeat the action until the patches come out clean. Set the gun aside until the barrel heat drys it off, then oil it well (inside and out). Fouling on the locks should be wiped clean with an oily cloth. Before using your muzzle loader wipe the bore clean.

LOADING THE PERCUSSION REVOLVER

Of the various percussion revolvers used during the Civil War, original versions of the two shown here, the 36 caliber Colt Navy and the 44 caliber Remington Army, were among the more famous. Later, when the war ended, many of these same pistols saw service along the western frontier. At that time when the country was young and wild, each man was expected to enforce his own law with a pair of "Six Shooters". A brace of these Colt Navies, or Remington 44's, did indeed carry weight.

REPLICA OF
36 CALIBER COLT NAVY

REPLICA OF
44 CALIBER
REMINGTON ARMY
Courtesy Navy Arms Company

.36 CAL. NAVY — SUGGESTED LOADS (#11 Alcan Caps)

* 	.375 ROUND BALL	25 grs. FFFG DuPont black powder (Vel. 1005 F.P.S.)
	BULLET #37583 145 Grs.	15 grs. FFFG DuPont black powder (Vel. 690 F.P.S.) Bullets must be sized from .001" to .002" over chamber diameter and lubricated (Lyman bullet lubricant).

.44 CAL. ARMY — SUGGESTED LOADS (#11 Alcan Caps)

* 	.451 ROUND BALL	39 grs. FFFG DuPont black powder (Vel. 995 F.P.S.)
	BULLET #450229 155 Grs.	26 grs. FFFG DuPont black powder (Vel. 815 F.P.S.) Bullets must be sized from .001" to .002" over chamber diameter and lubricated (Lyman bullet lubricant).

*MOST ACCURATE

1. Pour a measured amount of powder into each chamber.

Before you actually load your revolver it is wise to fire a percussion cap on each of the six nipples. This will remove any oil that may have accumulated in the nipples or chambers and insure ignition. After this is done, set the hammer of your pistol on the half-cock position and commence loading. Pour a measured amount of powder into each chamber and place a ball, or bullet, over the powder in the mouth of one of the chambers. DO NOT USE A PATCH. If you are loading a round ball, be sure that the sprue mark is up and carefully centered in the chamber. If you are using a conical bullet, even more care must be taken to make sure that the bullet is straight in line with the chamber.

2. Pull down on the loading lever to seat the projectile.

3. Fill the remainder of each chamber with heavy grease.

4. Place a percussion cap on each of the six nipples.

Carefully rotate the cylinder until the projectile is directly in line with the loading ram. Pull down on the loading lever and seat the projectile friction tight against the powder. As you load all six chambers, try to be consistent in applying the same seating pressure to each projectile. The next step is to fill the remainder of each chamber with a sufficiently heavy grease. This acts as a bullet lubricant and keeps bore fouling to a minimum. Lastly, you must prime the pistol by placing a percussion cap on each of the six nipples — and you're ready to fire. Before the gun is holstered the hammer is carefully let down and rested, not on the percussion cap, but on the raised portion of the cylinder between the nipples.

MISFIRES AND HANGFIRES

Although misfires seldom occur with modern cartridge weapons, they are quite common to muzzle loading arms. Several things can cause a misfire or hangfire: (1) Powder fouling can build up and close off the hole in the nipple. (2) Oil in the chamber might have dampened the powder charge. (3) Poor contact between the hammer and nipple might not set off the cap. (4) Poor quality percussion caps may not fire when struck by the hammer.

The best way to avoid misfires is to keep your gun clean and the nipples in good condition. Don't snap the hammer unless a cap is in place and use only good grade percussion caps.

If you should have a misfire, wait at least one full minute before you rotate the cylinder to reprime the nipple. A piece of thin copper wire is handy for cleaning the flash hole.

MULTI-IGNITION

Yes, it has happened and it can happen again. Percussion revolvers have been known to fire several chambers simultaneously. Oddly enough the results never seem to be as disastrous as you might think. Nevertheless, no matter how good your nerves are, it is best to take precautions. A tight fitting ball topped off with grease eliminates any chance of cross ignition in the front of the chamber. If your nipples are in good condition, and if you use the correct size percussion caps, cross ignition is unlikely at the back of the cylinder. One extra precaution is to smear a little Vaseline over and around the caps after they have been placed on nipples.

LOADING THE .58 RIFLED MUSKET

The original model of this rifle, the Remington Zouave Model 1863, saw service in the Civil War. Most experts still consider it one of the most accurate military percussion rifles ever produced. In the hands of many a civil war veteran, it helped to open the west by furnishing necessary food and protection.

REPLICA OF
REMINGTON ZOUAVE MODEL 1863
Courtesy Navy Arms Company

.58 CAL. MUSKET — SUGGESTED LOADS (Alcan 4 — Wing Musket Cap)

* 	MINNIE 575213 505 Grs.	60 grs. FFG DuPont black powder (Vel. 1005 F.P.S.) Bullets are not patched, but must be lubricated (Lyman Bullet Lubricant).
	.562 ROUND BALL	65 grs. FFG DuPont black powder (Vel. 1215 F.P.S.) Use .013 patch (linen if possible).

*MOST ACCURATE

Before actually loading the rifle, snap one or two caps on the nipple. This will insure ignition by clearing the nipple and vent of any oil that may have accumulated. Leave the hammer down on a spent cap and you are ready to start your loading. Keep the muzzle away from your body and expose as little of your hand as possible over the muzzle while loading.

Pour a measured amount of powder down the muzzle and hit the side of the barrel a few sharp raps with the heel of your hand. This will settle the powder in the barrel. Start the Minie ball (skirt down) into the muzzle with your fingers. Next, use your ramrod to push the bullet down tight against the powder. Remove the ramrod and cap your piece. You are now ready to fire.

MISFIRES AND HANGFIRES

If your rifle should ever fail to fire, be careful. Hold the muzzle down range and treat it as if it might go off at any minute . . . it could! After a few seconds reprime the nipple and try it again. A piece of thin copper wire is a handy tool for cleaning powder fouling from the nipple hole.

LOADING THE KENTUCKY PISTOL

A very few flint lock pistols of this design were made by the early riflesmiths of Pennsylvania. As they were not turned out in any great quantity, original Kentucky Pistols are exceptionally rare collector items today. The replica pistol illustrated here is available with either a flint or a percussion lock. Flint locks are, of course, more representative of the originals, but it would not be too unlikely to find even an original pistol that had been converted to percussion.

In as much as the loading procedure for the Kentucky pistol is essentially the same as that for the Kentucky rifle, we have included much of this information with the rifle section. We ask that you also read the following pages covering the Kentucky rifle. Loads for the pistols are considerably lighter than those for the rifles. For best accuracy with the pistol use only enough powder to get the ball to the target.

REPLICA OF
KENTUCKY PISTOL
Courtesy Navy Arms Co.

.44 CAL. KENTUCKY PISTOL — SUGGESTED LOADS

*  .424 ROUND BALL

#11 Alcan caps for percussions.

For flint locks fill pan cavity with FFFFG or FFFG.

40 grs. FFFG DuPont black powder (1050 F.P.S.) Use .013" patch (linen if possible). Start with the above charge and work downward. Best accuracy for your individual pistol will be somewhere below this charge. Our patch was spit lubricated.

*Best accuracy for individual pistol will require adjustment of charge.

LOADING THE KENTUCKY RIFLE

As distinctively American as corn bread or Daniel Boone, these rifles were made in Pennsylvania by German and Swiss riflesmiths who settled the region as early as 1710. The name "Kentucky" was given to the weapon because of its popularity in the then unsettled wilderness of Kentucky and Tennessee. The complete development of the Kentucky rifle was slow. It required almost a hundred years of evolution and changes before its design developed into the long flowing beauty that we recognize so readily today.

The replica rifle illustrated here is available with either a flint or a percussion lock. Although the early originals were all flint locks, many were converted to percussion over the passing years.

REPLICA OF
KENTUCKY RIFLE

.40 CAL. KENTUCKY RIFLE — SUGGESTED LOAD

* .395
ROUND BALL

#11 Alcan caps for percussions.

For flint locks fill pan cavity with FFFFG or FFFG.

40 grs. FFFG DuPont black powder (Vel. 1745 F.P.S.) Use .013 patch (linen if possible) and spit lubricated. With our test rifle, this load shot one hole groups at 50 yards.

*SUPERB ACCURACY

Before actually loading your rifle, snap one or two caps on the nipple. If your rifle has a flint lock, strike a pan of powder with the bore unloaded. This will insure ignition by clearing away any oil that may have accumulated in the drum or vent. Set your rifle on its butt stock and hold the muzzle away from face and body. Pour the measured amount of powder down the muzzle and hit the side of the barrel a few sharp raps with the heel of your hand. This will settle the powder in the barrel.

Select a piece of patching, wet it well on your tongue and place it over the muzzle. Lay a ball on the patching. Uniformity is important and you should make certain that the grain of the patch is always in the same direction. Also, be sure that the sprue mark on the ball is up and centered in the bore. Start the ball (flush with the muzzle) by using your short starter. Now, with a sharp knife, or old-fashioned straight razor, cut off the excess patching material. The ball should now be flush with the muzzle and encased in a neat circular patch of cloth. If the ball is tight, a long starter should be used to drive the ball about four inches down the barrel.

Complete the job by using the ramrod to push the ball the rest of the way to the powder. Seat the ball firmly against the powder, but do not pound the ball or crush the powder in the process. Once the ball is loaded, it is wise to mark your ramrod at the muzzle. This will give you a reference mark for future loading.

The last thing you do is prime the piece. If your rifle is a cap lock, place a cap on the nipple and press it all the way down for uniform ignition. If your rifle is a flint lock, open the frizzen and pour a small amount of priming powder (FFFFG) into the pan. Close the frizzen and she's ready to go.

MISFIRES AND HANGFIRES

If your rifle should ever fail to fire, be careful. Hold the muzzle down range and treat it as if it might go off at any minute. After a few seconds, reprime the gun and try it again. A piece of fine copper wire is a handy tool for cleaning powder fouling from the nipple. It is handy, too, to pick a few grains of fresh powder into the drum or frizzen, if the rifle doesn't fire.

LOADING THE MUZZLE LOADING SHOTGUN

In granddad's day a shotgun was not considered a piece of luxury sporting equipment. His old scattergun was a basic household tool that had the vital function of putting "meat in the pot". Many of the original guns still bear signs that attest to the hard use to which they were put over the years. Their hammers and lock parts have been repaired or replaced, and their ancient barrels have been worn thin from countless firings.

When firing a muzzle loading shotgun for the first time, most shooters are surprised to learn that granddad really wasn't handicapped by his old smooth-bore. Many of these old guns are nicely put together and you have only to shoot them to appreciate their superb balance and handling speed. For a hunter who wants maximum sport at a minimum cost, a replica of these old coal burners just can't be beat.

REPLICA OF
MUZZLE LOADING SHOTGUN

20 GA. SHOTGUN — SUGGESTED LOAD (Alcan #11 Caps)

CHARGE — 2-1/2 drams FFG black powder
FILLER WADS — 2 Rem. 3/8" 20 ga. felt wads
SHOT — 1 ounce #9
OVER SHOT WAD — 1 Rem. 3/16" 20 ga. felt wad
(Vel. 1050 F.P.S. — pattern good

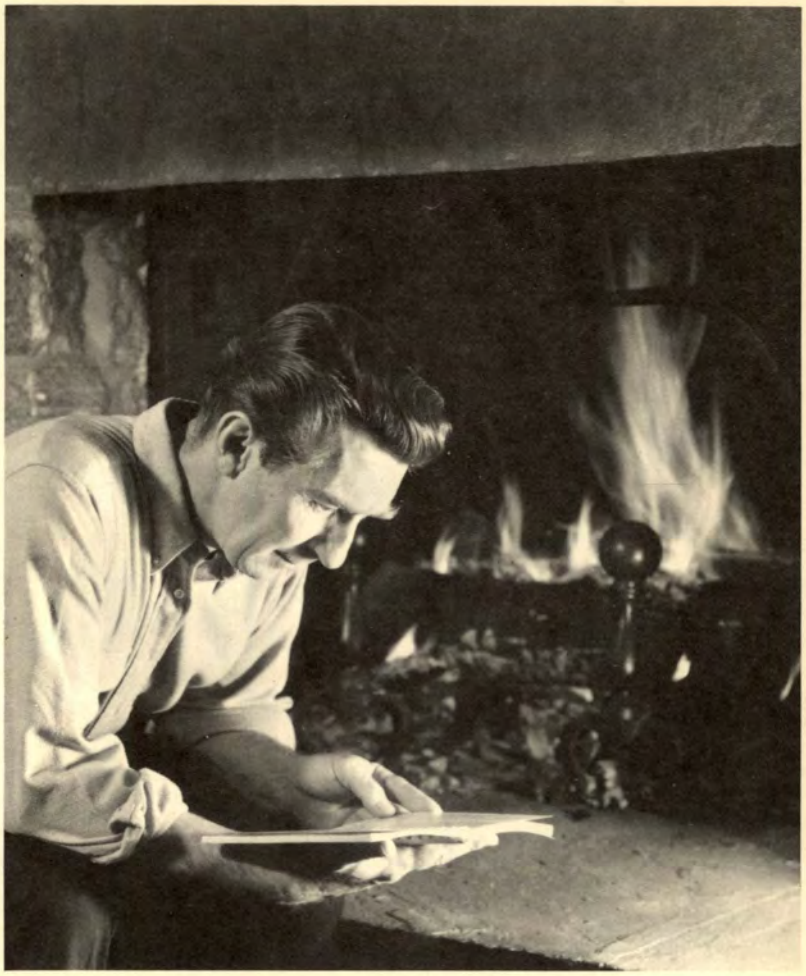
LOADING AND CARE OF THE MUZZLE LOADING SHOTGUN

Loading the muzzle loading shotgun is simple, for the proportions are equal measures of powder and shot. The Lyman adjustable shot dipper serves as a measure for both powder and shot. For wads, the shooter may purchase any standard commercial type. He may also cut his own wads from available material with a Lyman wad cutter.

Over powder and over shot wads can be cut easily from any hard cardboard. Filler wads must be thicker and softer and a suitable material is somewhat harder to come by. Solitex board works, but it is perhaps more desirable to purchase your filler wads.

Before loading your gun, snap several caps to clean the oil from the nipples. Leave both hammers down on two of the spent caps and begin loading. Pour into each barrel a measured amount of powder, then push the over powder wad down firmly on the powder. On top of this, load the filler wad into each barrel and pour in the measured shot charge. The shot charge is covered with an over shot wad to keep it from rolling out the barrel. To insure against it upsetting under recoil, the over shot wad should fit tightly. Lastly, prime your piece by placing both hammers on half-cock and a cap on each nipple. That's it! She's ready to shoot.

CAUTION: If only one barrel is fired and it is desired to reload, the cap should always be removed from the charged barrel.



Reference Section

This section contains the following chapters:

- **PRESSURE**
- **POWDERS**
- **CASES**
- **PRIMERS**
- **BULLETS**
- **ACCURACY WITH JACKETED BULLETS**
- **ACCURACY WITH CAST BULLETS**
- **UNDERSTANDING VELOCITIES**
- **RELOADING ACCESSORIES**
- **GLOSSARY OF TERMS**

We strongly urge you to read these chapters carefully and familiarize yourself completely with their contents. Periodic rereading will allow you to commit much of this information to memory, and assure you a sound, safe knowledge of the subject.

Our very special thanks to those people who through their cooperation, interest and encouragement helped immeasurably in producing this Handbook.

THE LYMAN GUN SIGHT CORPORATION

PRESSURE

The format and cross reference of this Handbook is designed to accomplish certain objectives. One of the most important of these is to direct your attention to this chapter on Pressure. We urge you to read it carefully and to follow our recommendations when working with maximum loads.

Some reloaders who might otherwise be considered "safe and sane", open a reloading manual, hastily select a load marked "Maximum Velocity", then throw the indicated powder charge into a primed case, seat a bullet and fire away. This is not the right way . . . it is the **dangerous** way!

Although the mechanical procedure for reloading is relatively simple, learning the difference between the right way and the wrong way requires some homework. To enjoy this hobby, you must learn the rules . . . know the limits within which to stay for safety. Therefore, a basic knowledge of pressures is necessary.

WHAT IS PRESSURE?

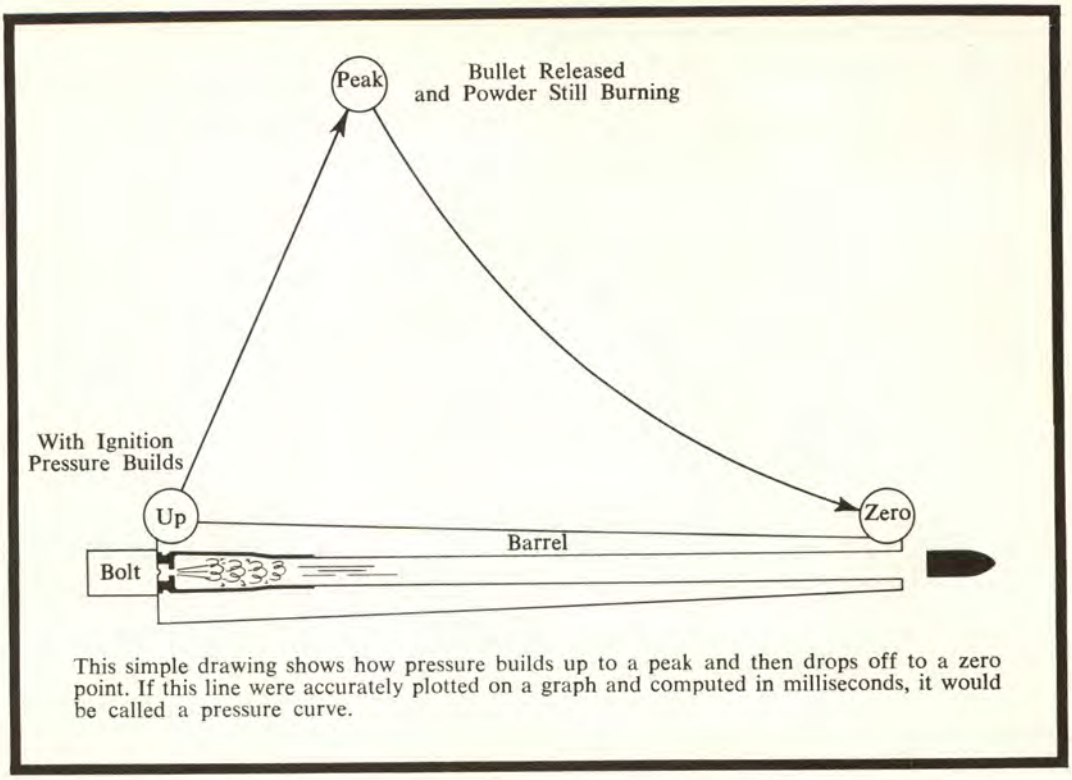
Let's not begin by assuming that all pressures are dangerous. Of course, they are not. Pressure is the power that drives the bullet down the barrel and out to the target. Without a considerable amount of controlled pressure, the cartridge would not function.

Neither should it be assumed that all high pressures, even safe ones, are desirable. The hottest load is rarely the most accurate one, and high pressures do shorten barrel and case life. Pressure, therefore, is something that can be manipulated, but we must first understand what we are trying to accomplish.

Pressure in the cartridge case begins with the primer flash. The powder upon ignition rapidly generates an enormous amount of gas creating pressure in all directions. It presses against the case head and drives the cartridge back against the bolt. It forces the case walls out tight against the sides of the chamber. It pushes forward on the bullet base.

Naturally, as the pressure builds, the gas seeks to escape the confines of the case. The case head and walls, being supported by the bolt and chamber, refuse to budge. This leaves only one direction for the gas to exit. So it forces the bullet out of the case and drives it with increasing speed down the barrel.

From the time of ignition, and before there has been time for any appreciable bullet movement, the peak pressure has been reached. After this, a gradual decrease in pressure takes place until the bullet emerges from the muzzle. At this point, the pressure returns quickly to zero. This sequence of events takes place in an extremely short period of time. What concerns the reloader, is just how **high** this pressure climbs, and how **safely** it is controlled during firing.



This simple drawing shows how pressure builds up to a peak and then drops off to a zero point. If this line were accurately plotted on a graph and computed in milliseconds, it would be called a pressure curve.

If all a reloader had to be concerned about was the amount of powder to pour into a case in order to obtain a given peak of pressure, it would all be quite simple. Unfortunately, it's not that easy. Although the powder charge creates the pressure in the cartridge, other factors such as the primer, bullet weight, bullet hardness, bore size, etc., will alter the height, shape and location of the pressure peak. These factors, collectively or individually, can raise pressures considerably, and even carry them into a danger zone. For example, the maximum charges listed in this Handbook could, if they were affected by the wrong set of circumstances, produce unsafe pressures in your particular rifle. As you study this chapter, you will see how all this is taken into account when working out maximum charges. At this time, however, let's just remember that less powder does not always mean less pressure. In some rifles, and under certain conditions, the same maximum pressure can be attained with far less powder than the maximum charge.

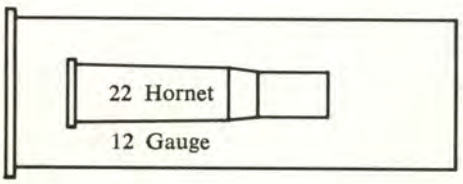
WORKING PRESSURE

Simply stated, working pressure represents the strength of your cartridge case. All factory loaded cartridges for rifles, handguns, and shotguns are loaded to operate within a specific pressure range. This is known as the "Maximum Working Pressure" for a particular cartridge. Depending on the design requirements of the individual cartridge, working pressures will vary. For example, the 300 H & H Magnum has a higher working pressure than, say, the 30/30, and pressures for the 44 Magnum are higher than those of a 38 special.

The working pressures of a cartridge is usually expressed in terms of thousands of pounds **per square inch**. This means that the cartridge case, when properly chambered in

a firearm designed for it, will under normal circumstances, safely control pressures up to its rated pounds per square inch. The reloader should remember, however, that these pressure figures established under controlled conditions can only be safely duplicated using guns and cases that are mechanically sound. They cannot be safely duplicated in guns with poor chambers, or with any old cartridge case.

The maximum working pressure is dictated to some extent by the size of the gun chamber. All other conditions being equal, a small chamber will withstand a higher pressure than a large one, simply because there is less area (fewer sq. inches) for pressure to work against. A 12 gauge shotshell, for example, may have a working pressure of only 11,000 pounds P.S.I., but it has a far greater case area than, say, a 22 Hornet case with its 43,000 pounds P.S.I.



Safe working pressure depends on both the strength of the case and the strength of the rifle. A cartridge such as the 300 H & H Magnum, uses a very heavy walled case which enables it to withstand pressures up to as high as 55,000 pounds P.S.I.

Rifles for these cartridges are built with very strong bolt actions of heat treated alloy steel. The 30/30 cartridge, however, might be viewed as the opposite extreme. Although these rather thin walled cases have been beefed up somewhat over the years to increase the safety factor, they still must be restricted to a more moderate pressure of under 40,000 pounds P.S.I. This is due to the weaker design of the various guns which are chambered for this cartridge.

Every rifle and cartridge combination fits somewhere in the overall picture of maximum working pressure. The reloader, because he is not certain of where he stands in relation to his maximum pressure, should work slowly. He should begin with a safe starting load and work carefully upwards to establish the maximum charge for his particular rifle and case combination. All of the maximum charges listed in this Handbook have been tested and fired by our technicians. They were found to be maximum in our rifles and under our conditions. Under no circumstances should the reloader exceed these loads, nor should he quickly accept them as **his** maximum.

CONTROLLED PRESSURE

The average reloader does not have access to elaborate pressure testing equipment. To determine his area of safe pressure, he must work with a reloading manual and a good bit of common sense. As he gains in knowledge from both study and experience, he applies it directly to his loading conditions, and he works up good, safe, accurate loads for his particular firearm. These might not be the hottest loads possible. In most cases, if we're concerned with accuracy and barrel life, these loads will probably remain a little on the mild side.

In working up to your maximum load, it is recommended that you follow this procedure:

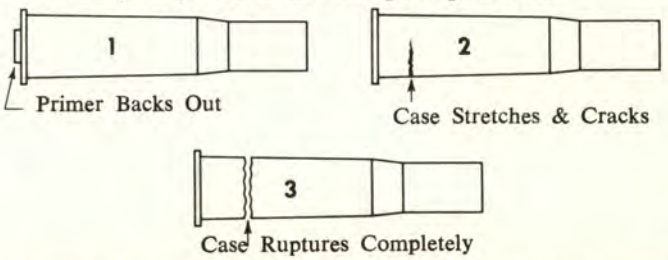
1. Begin with the suggested starting load listed in this Handbook. Do not start with the maximum.
2. Weigh all your loads on a powder scale. Do not use a powder measure until after you have firmly established the safety of your load.
3. Increase your charges in gradual increments: ½ grain at a time for charges over 25 grains; 1/10 grain for charges under 25 grains.
4. Fire no less than five rounds each time you increase your charge.
5. Use only new or once fired cases when working up a load and be fussy with them. Inspect your cases thoroughly after each firing.
6. Wipe all the sizing lubricant off your cases before firing. The presence of lubricant will cause excessive thrust on the bolt face.
7. Never mix brands of individual components. If you change a primer brand, case brand, bullet, etc., start all over again. You probably have changed your pressure.
8. Do not exceed the maximum listed load.
9. Always wear a good pair of shooting glasses when firing test loads.

The remainder of this chapter covers the various factors that can alter your chamber pressure. It will also enable you to recognize signs of excess pressure. Study the text carefully, as you must be able to recognize and interpret the signs before you can work in a maximum pressure area. If you should encounter definite signs of excess pressure . . . reduce your powder charge immediately . . . a full 10 percent. If you have indefinite indications of excess pressure, do not go higher until you determine exactly what is causing the problem. If you have difficulty finding the solution to a problem, write to us. We will be happy to offer our assistance.

HEADSPACE

To withstand normal chamber pressure, the head of your cartridge case must be firmly supported by the bolt face and chamber wall. Without this support, the brass case stretches beyond its normal limits. The case will then rupture and free hot powder gas into the action of the rifle. When excessive headspace is present, the bolt does not support the case head.

While excessive headspace will not boost the pressure in your chamber, it will destroy your rifle's ability to handle even moderate pressure. As reloaders, we must first assure ourselves that our rifle is completely free from headspace problems.



The above illustrations are indications of excessive headspace. Do not use any firearm which shows such signs of headspace problems.

At low pressure (the starting load) the first sign of excessive headspace is usually the backing out of primers. As the pressure of the load increases, the case stretches to the point of cracking around its circumference. This stretching is sometimes so severe that the entire head of the case separates from the case body allowing the gas to flow back through the action.

Check your present cases for primer back-out and for cracks and splits. If your cases do not show signs of excessive headspace with the loads you are using, you may assume that your rifle is headspaced correctly. If these signs do appear at any time, see a competent gunsmith. Have him check your rifle and your reloading dies. A poor sizing die which shortens the shoulder of the case, can also cause the same problems as excessive headspace in your rifle.

CONDITIONS WHICH CAN RAISE PRESSURE

POWDER

Adding more powder to the case will obviously create higher pressure. Reduced charges may also boost pressure if the powder is not compatible with the load (see Detonation). Fast burning powders create higher pressures than slow burning powders when used in equal amounts (see Powder chapter). You must select the type of powder designed for your purposes. The powders shown in this Handbook were carefully chosen for the calibers and loads listed.

DETONATION

First let us consider that the term "detonation" may be a misnomer when used in connection with gun powder. Propellent powders, if used correctly, will burn. They will not explode or detonate. The word "detonation", however, is in popular use so we will use it here to avoid confusion.

When some powders are used for reduced loads, they will jump pressure enormously. In some instances such pressures will wreck the gun. Why? We admit that we do not know and no ballistics engineer has yet come forward with the answer. The point is that if conditions are right it can occur; therefore the reloader should never reduce the suggested starting loads listed in our Handbook. For reduced loads, use only cast lead alloy bullets in accordance with the data recommended. **Never guess** concerning the burning characteristics of powder.

BULLETS

All things being equal, the heavier the bullet, the greater the increase in pressure. Harder bullets, likewise, boost pressures due to their greater resistance to the rifling. Oversize bullets, and bullets with more bearing surface, will also up pressure.

CASES

All cartridge cases do not have the same inside capacity. Some cases, such as G.I. brass, have heavier walls which reduce the inside dimension of the case. Whenever you reduce the inside dimensions and use the same powder charge, you immediately boost pressure. Assorted brands of cases, when used with the same powder charge, will usually give variations in pressure.

PRIMERS

Primer burning time will add to the pressure. When working up a load, you should be consistent in using the same brand and type of primer. (See Primer chapter).

DEEP SEATING BULLETS

Oddly enough, our testing indicates that considerable variations in the seating depth of jacketed bullets does not appreciably increase or decrease pressure. Lead bullets will, however, up pressures when they are seated too deeply. The base of a lead alloy bullet has a tendency to expand when it is seated below the shoulder.

OVERALL LENGTH

Seating the bullet too far forward does raise pressure. In this instance, the bullet is bumping the rifling and it is receiving far greater resistance at the time of ignition. Watch the seating depth carefully and adhere to the overall cartridge length listed.

CHAMBER AND BORE DIMENSIONS

Pressure for a given load varies with the tolerance of the individual rifle. The condition of the throat, rate of twist, bore diameter, groove diameter, and chamber dimensions, etc., all affect overall pressure. The tolerance range for domestic rifles has been taken into consideration when determining the suggested **starting loads** in the Handbook. If your rifle is imported, however, (Sporter or Military) we suggest that you slug the barrel before attempting to reload. The bullet you use should correspond exactly to the groove diameter of your rifle. In some instances jacketed bullets which do not exceed .002″ over or under this diameter are permissible. Cast bullets can vary .003″ over or under the groove diameter.

READING PRESSURE SIGNS

As you work up to a maximum loading, adding powder gradually to the charge, watch closely for signs of excess pressure. Carefully inspect each cartridge case after it is fired. If your cases show no signs of excess pressure, continue adding another increment of powder to your total charge until you reach your best performing load. Fire each load for accuracy and be critical of any after effects. If accuracy falls off as you increase the charge, why go higher? You have found the load that performs best in your particular rifle. **Never exceed the maximum load listed.**

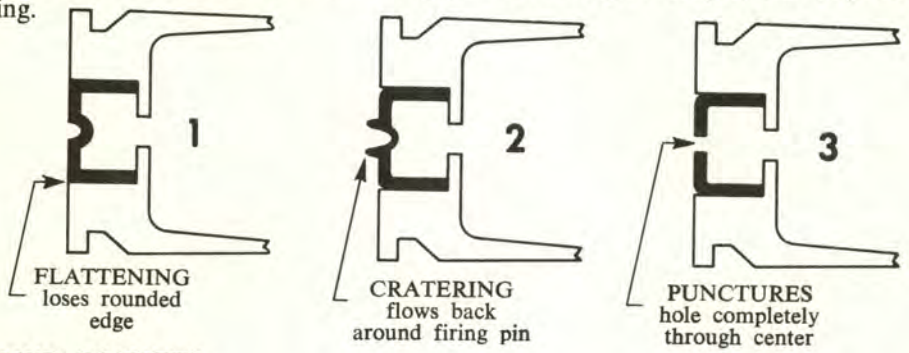
As you continue to use your maximum load, your cases will start showing signs of normal wear. The case brass will eventually fatigue and small cracks will appear in the necks or walls. Primer pockets will enlarge to a point where primers can be seated by thumb pressure. **These are not signs of excess pressure** (see Case chapter). Your cases have merely worn out and they are ready for the scrap heap. To differentiate between fatigued brass, and pressure, is not always easy, and for this reason only new cases should be used for working up your maximum charge.

The following text and examples deal with pressure signs as they might appear when working with new brass. Some of the signs are definite indications of excessive pressure — others are not. All signs, however, should be considered as evidence of pressure until proved otherwise. Collectively, they should always be considered as a sure indication of excess pressure.

PRIMERS

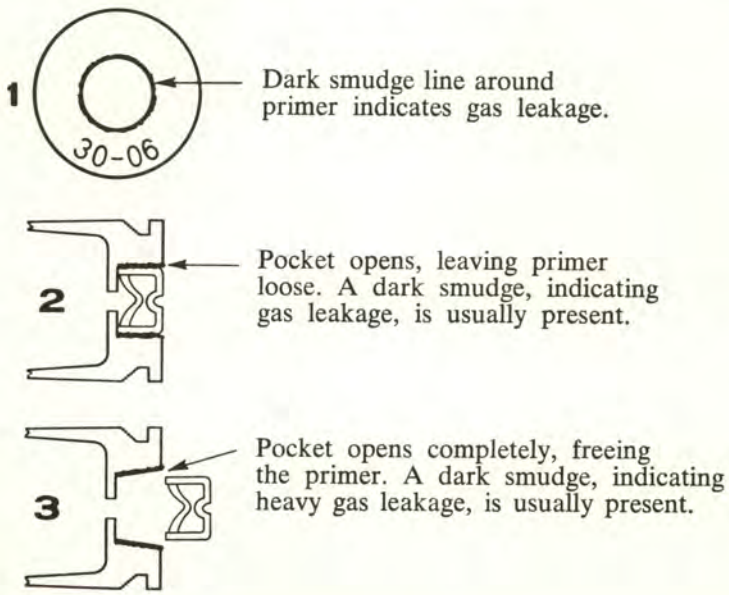
Some reloaders claim that little can be learned by examining fired primers. This is not so. A change in primer shape is usually one of the first indications that all is not well. Although soft primers will give false evidence of pressures, they are not normally encountered. Common sense tells us that we must stick to the same brand and type of primer when developing a load. By so doing, if we start with the suggested starting load without encountering pressure signs, and work up to a point where we suddenly note a change in primer contour — then it's obvious that something has happened!

The following drawings illustrate several changes in primer contour which indicate pressure problems. However, these changes may have been caused by other factors. For example, the change shown in drawing No. 3 may have been caused by a long firing pin. Common sense again tells us that a firing pin does not grow longer, half way through our testing.



PRIMER POCKETS

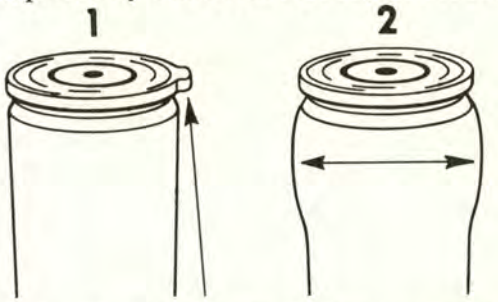
As the pressure grows, the head of the case is subjected to more and more stress. This will eventually open the primer pocket and force the primer out. Usually the first indication of this is a dark line (caused by gas leakage) around the primer. These signs may also indicate case fatigue, but remember, we are using **new** cases.



HEAD EXPANSION

The side walls and neck of the cartridge case are designed to expand freely. This expansion is necessary to seal off the chamber and prevent gas from leaking back between the case and the chamber wall. It also frees the bullet for its flight down the barrel. When a fired cartridge case is badly smudged by gas on its outer walls and neck (without other indications) it is actually a sign that the pressure is too low, and the case walls are not expanding properly.

Head expansion, however, is something else again. To fulfill its function, the case head must remain fairly rigid. Any flattening of the case head, or the flowing or expanding of brass in this area, is definitely a sign of very high pressure. The telltale signs in the illustrations below are often accompanied by other evidences of pressure such as blown primers and escaping gas.



Brass Flows Back Into Extractor Port — Head Stamping Flattens — Head Shows Irregularities of Bolt Face.

Case Expands In The Head Area.

A good micrometer is required for checking the head expansion illustrated in example No. 2. Normally, expansion of .001″ is considered evidence of very high pressure. Some rifles, however, (depending on their individual chamber dimension), will show some case expansion even with factory ammo. The best method is to fire a few factory loaded rounds through your rifle and measure the expansion of the brass. This can then be accepted as norm and any expansion over it should be considered excessive.

HARD EXTRACTION

If experienced suddenly, hard extraction is a definite sign of high pressure. A rough chamber might also create an extraction problem, but this would be obvious by its consistency.

VISIBLE GAS LEAKS

On very low pressure loads, when the case walls are not expanding properly, gas leakage may be visible (see head expansion). Under any other condition, however, this is a definite sign of high pressure. Look for blown primers, stretched pockets, etc.

CONCLUSION

To summarize, we suggest that you practice common sense and conservatism when working with maximum loads. Learn about pressure factors as they affect your particular gun. Don't guess. Don't be careless. Stalk your pressure limits, don't jump at them.

Specifically, consider these factors: if the accuracy of your load is good, if your case life is relatively long, if you haven't had undesirable signs of pressure when working up the load . . . then your pressures, whatever they are, are probably perfectly safe.

Also, we recommend that you read the chapters on Powder, Cases, etc., which are all part of this Reference Section. Those interested in shotshell pressures should also read Shotshell Ballistics and Tips chapter.

POWDER

The reloader is concerned with three relatively basic aspects of gun powder. One, he must select his powder wisely to assure that he has the proper powder for the job intended. Two, he must handle his powder with the care that common sense dictates. Three, he must store his powder in adherence to a few simple precautions that are necessary if the powder is to retain its usefulness and to prevent its presence from becoming a fire hazard.

SELECTING POWDER

Your Lyman Handbook will guide you in the proper choice of a powder for your particular cartridge. The data page which lists your cartridge also shows the various powders which we tested in this cartridge. In every instance, the application of these powders was chosen with care. The data page will also supply the suggested starting charge that we recommend with each powder and bullet weight listed.

Never assume or attempt to guess at the burning characteristics of a powder. This could lead you to trouble. Depending on their application, powders can change their burning characteristics rather drastically. The chemical compositions of the powder, the shape and size of the powder particle plus the density, or porosity of the powder composition do control its burning rate. Other factors, however, such as the degree of confinement, the heat of ignition, the temperature of the combustion chamber and the density of loading all effect the burning rate and must be carefully considered.

Our advice in selecting powder is never use any powder unless you are **positive** of its identity and then use this powder in accordance with printed data from a reliable source. Never exceed maximum loads, and never reduce starting loads. The listing of powders in this chapter does not represent all the powders available to the handloader. Nor does it show all the possible applications of listed powder. It is simply a listing of the powders which we used in compiling data for this Handbook. Testing time and space prevented the complete listing of every powder with every possible application. For more information on a specific powder we suggest that you contact its manufacturer.

HANDLING AND STORAGE

Powders should be stored in a cool, dry place out of the reach of children. They should never be left in a powder measure but returned to their original factory containers where they remain **clearly marked** until you are ready to use them again.

Naturally powder will burn and therefore, all normal cautions which apply to flammable commodities should be adhered to, keeping smokeless powder away from open flame, sparks, refraining from smoking while loading and general common sense is all that is required.

Black powder is a bit more touchy than smokeless powder, and in addition to the foregoing, it can be ignited by percussion. Black powder should be handled in such a manner as to prevent it from being banged around. The use of black powder in a powder measure is not recommended.

DU PONT BLACK POWDERS

FFFFG — Normally used only for priming flint lock pans.

FFFG — This was the finest granulation we used for our testing. Excellent in pistols and smaller caliber rifles. Also used for priming the flash pan on flint locks.

FFG — This granulation was used for the .58 caliber muzzle loading rifles and also for the muzzle loading shot gun.

FG — Normally used in very large caliber muskets.

DU PONT SMOKELESS POWDERS

HI-SKOR 700-X — This clean burning double base powder is used both for shot shell and pistol loading. In shot shells optimum ballistics are obtained with minimum charge weights. In pistol cartridges it produced very accurate target loads in calibers from .38 to .45. Available in 1/2 lb. canisters, 5 lb. caddies, and 12 lb. kegs.

PB — This porous base powder is used very successfully for both shotshell and pistol loading. It is a very versatile powder lending itself to loads from 28 gauge to 12 gauge and a wide range of handgun cartridges. Available in 1/2 lb. canisters, 4 lb. caddies, and 25 lb. drums.

SR-7625 — This single base powder has proven itself over a wide range of loading applications both in shotshell and pistol cartridges. Excellent results were obtained throughout our testing. Also used successfully for some cast bullet rifle loads. Available in 1/2 lb. canisters, 4 lb. caddies, and 25 lb. drums.

SR-4756 — This relatively slow burning powder is used predominately as a shot shell propellent. It serves as an excellent powder for heavy field loads. In some instances it was used very successfully with handgun cartridges. It is also used as a cast bullet propellent in some rifle cartridges. Packaged in 1/2 lb. canisters, 4 lb. caddies, and 25 lb. drums.

IMR-4227 — Here indeed is a versatile powder. It is used for a wide range of shotgun, pistol, and rifle cartridge loading. A very excellent powder for use with cast bullets in most rifle calibers. This powder, which is the fastest burning of the IMR series, is available in 1 lb. canisters, 8 lb. caddies, and 20 lb. kegs.

IMR-4198 — This powder was developed especially for small and medium capacity rifle cartridges. It is also used successfully in straight walled cases. Very excellent accuracy is

obtained in the .222 Remington and similar cases when using this powder. It is also used for a number of cast bullet rifle loads. Available in 1 lb. canisters, 8 lb. caddies, and 20 lb. kegs.

IMR-3031 — This powder, which the manufacturer recommends specifically for medium capacity cartridges, has proven very versatile. Excellent accuracy was had when used in cases such as the .243, .250/3000, .308, and .358 Winchester. In some rifle calibers this powder also performed well with cast bullets. Available in 1 lb. canisters, 8 lb. caddies, and 20 lb. kegs.

IMR-4895 — This powder has proven itself as a standard for .30 caliber military cartridges. An all time favorite, this powder has proven very versatile and measures uniformly through the #55 Powder Measure. In most cases very uniform ballistics and excellent accuracy was common. Under most circumstances it burns slightly faster than #4320 and is available in 1 lb. canisters, 8 lb. caddies, and 20 lb. kegs.

IMR-4064 — This powder burns exceptionally uniform in most medium and large capacity cases. Very excellent results were obtained in cases such as the .375 H & H Magnum. Also very popular with varmint shooters in such cartridges as the .243 Winchester and .244 Remington. As with all the IMR series, this powder is available in 1 lb. canisters, 8 lb. caddies, and 20 lb. kegs.

IMR-4320 — This excellent IMR series powder is relatively slow burning, and has proven quite adaptable in a wide range of loading usages. Favored by many reloaders for the heavier bullets in moderate and large capacity cases. Available in 1 lb. canisters, 8 lb. caddies, and 20 lb. kegs.

IMR-4350 — This is the slowest burning of the IMR series. Best suited to large capacity magnum type cases and to the heavier bullets in medium size cases. However the versatility of this powder permits it to be loaded into a wide range of cases, from the .220 Swift, to the .460 Weatherby Magnum. Available in 1 lb. canisters, 8 lb. caddies, and 20 lb. kegs.

HERCULES POWDERS

BULLSEYE — This very popular pistol powder delivered excellent accuracy throughout the complete range of pistol cartridges. This is the fastest burning powder in the Hercules line and is best suited to target type loads. It is available in 11 ounce canisters, 3 lb. kegs, and 15 lb. kegs.

RED DOT — Our use of this powder was similar to that of Bullseye. In some handgun cartridges it proved to be very accurate. Available in 8 ounce canisters, 3 lb. kegs, and 12 lb. kegs.

UNIQUE — This powder is a very excellent choice for use with cast bullets both in rifle and handgun cartridges. Very fine accuracy was obtained throughout the wide range of cartridges tested. This powder also proved useful when trying to duplicate factory velocities in cartridges such as the .38/40. Available in 13 ounce canisters, 4 lb. kegs, and 15 lb. kegs.

2400 — Here is another powder which proved very accurate, when used with cast bullets, through a wide range of rifle and pistol cartridges. An excellent choice for use with jacketed bullets in the .22 Hornet. Available in 1 lb. canisters and 5 lb. kegs.

HERCO — The coarse grained powder proved useful in a variety of pistol cartridges. Available in 1 lb. canisters, and 5 lb. kegs.

RELOADER 7 — This is the fastest burning of the Reloader series powder, and also the smallest in granulation. This powder provided very excellent accuracy in the .32 Remington, .32 Winchester Special, and the .35 Remington cartridges. Available in 1 lb. cans.

RELOADER 11 — This double base powder is useful in a large number of rifle cartridges. It is available in 1 lb. cans.

RELOADER 21 — This is the slowest burning powder in the Reloader series. It is best suited to the larger capacity cases. Available in 1 lb. cans.

ALCAN POWDERS

AL-5 — This dense progressive shotshell powder proved useful in the 20 gauge shells, as well as the 12 gauge Alcan cases. Available in 1/2 lb. tins, 3 lb., 6 lb., and 15 lb. kegs.

AL-7 — Another dense progressive shotshell powder which proved useful through a wide range of shotshell loadings. Available in 1/2 lb., 3 lb., 6 lb., and 15 lb. kegs.

AL-8 — This is a coarse grained powder that is designed basically for the heavier shot loadings. It is also excellent in the .30 M1 Carbine. Other uses included the .44 Magnum cartridge. Available in 1/2 lb tins, 3 lb., 6 lb., and 15 lb. kegs.

HODGDON POWDERS

H110 — This fast burning spherical powder proved useful in the .25/20 cartridge. Available in 1 lb. cans, and 20, 50, and 100 lb. kegs.

H335 — This spherical powder proved adaptable to a number of calibers. Loads should be worked up with extreme caution as pressures tend to take large jumps suddenly. Ignition problems were encountered in guns having a light firing pin fall. Available in 1 lb. cans, and 20, 50, and 100 lb. kegs.

Ball C#2 — This spherical powder is popular with a large number of shooters. The same cautions which apply to the H335 are applicable to Ball C#2. Available in 1 lb cans, and 20, 50, and 100 lb. kegs.

H380 — The spherical powder produced very uniform ballistics and excellent accuracy in a great many calibers. Especially suggested for jacketed bullets in the 7.35mm Italian (Terni) rifles. Available in 1 lb. cans, and 20, 50, and 100 lb. kegs.

H450 — The powder, a spherical one, is very well suited to large capacity magnum type cases. It was the only powder with which we were able to duplicate factory ballistics in the .308 Norma cartridge. Available in 1 lb. cans and 20, 50, or 100 lb. kegs

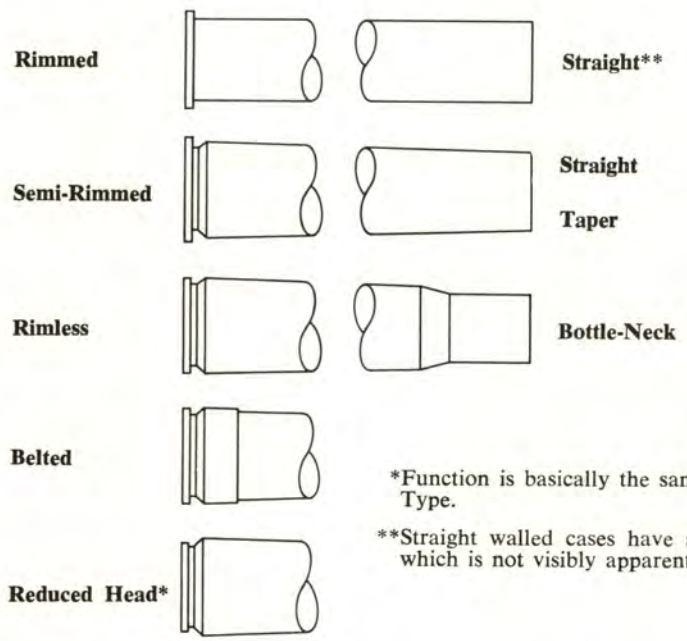
4831 — This powder is probably the most popular powder in the .264 Winchester Magnum and other similar large capacity magnum cases. It proved to be very accurate and delivered uniform velocities when used in the large capacity cases. Available in 1 lb. cans, and 20, 50, or 100 lb. kegs.

CASES

By the time your interest in shooting has advanced to the point where you are seriously considering handloading, you are already quite knowledgeable. At least you have purchased, handled and fired a good many rounds of factory loaded cartridges. This experience has given you a working knowledge of the various caliber designations and cartridge shapes, and you have learned to recognize the correct cartridge for your particular rifle. However, you have probably regarded your cartridge case as merely a container which held a packaged charge. After the charge had been fired, the case was discarded. The condition of the case after firing was of little concern to you.

Of course, in reloading we are particularly concerned with the condition of our empty cartridge cases because they now become reloadable components. Their condition after firing affects the safety and performance of our finished reloads. To appreciate fully the importance of the cases as reloading components, it is necessary that we learn about their composition and characteristics.

CASE STYLES

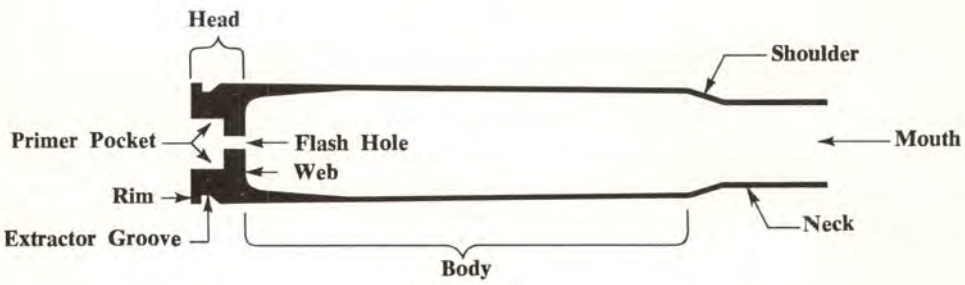


*Function is basically the same as Rimless Type.

**Straight walled cases have a slight taper which is not visibly apparent.

Showing the various head forms and body shapes standard to cartridge design. You can find a case example for almost any combination shown. For instance, a 30/30 has a rimmed, bottle-neck case, whereas the 458 Winchester has a belted head and straight body.

NOMENCLATURE OF A CARTRIDGE CASE



Nomenclature of a bottle-neck rifle case. While cases vary in shape and size, the same basic nomenclature applies to all center fire cartridges.

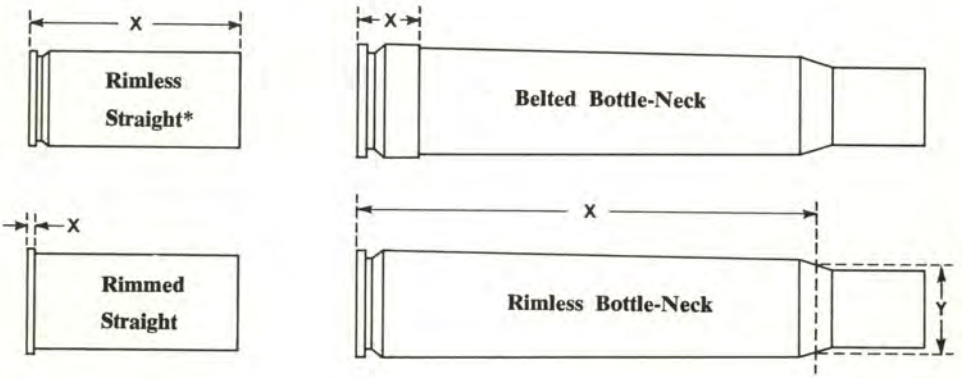
The most important function of the cartridge case is to seal off the breech and to safely handle the pressure which is built up during firing. Naturally, a brass case by itself is not strong enough to do the job. Supporting strength provided by the steel chamber walls and bolt face is also required. The case itself, however, must be capable of carrying its part of the stress load. To accomplish this the case must be in good condition and it must fit the chamber dimensions of the firearm.

If the cartridge case is to properly fit the chamber dimension of the firearm, it has to be made to extremely close tolerances. Two of these dimensions, **overall case length**, and **headspace**, are critical to the safety of the load whether it is an original factory load, or a reload. Handloaders must understand the importance of these two dimensions and respect them for what they indicate.

HEADSPACE

Headspace in a rifle chamber and in a cartridge case is exactly the same. It is the distance from the bolt face (or case head) to that part of the chamber (or case) that acts as a stop which keeps the loaded round from moving forward. In both instances, (chamber and case) this measurement is one of length. If it is not held to a close tolerance, the cartridge case will enter the chamber too far and lose the support of the bolt face. This condition would be termed "excessive headspace."

Depending on its case design, the headspace requirements of a cartridge will vary. A rimmed cartridge, for example, uses its rim to stop forward movement in the chamber. Others use different portions of the case such as the shoulder, mouth, etc. The following illustration indicates how headspace is measured with various case designs.



The design of the case governs the headspace dimensions. Note how X indicates headspace on three of the above examples, while X and Y are the controlling factors on the rimless bottle-neck example.

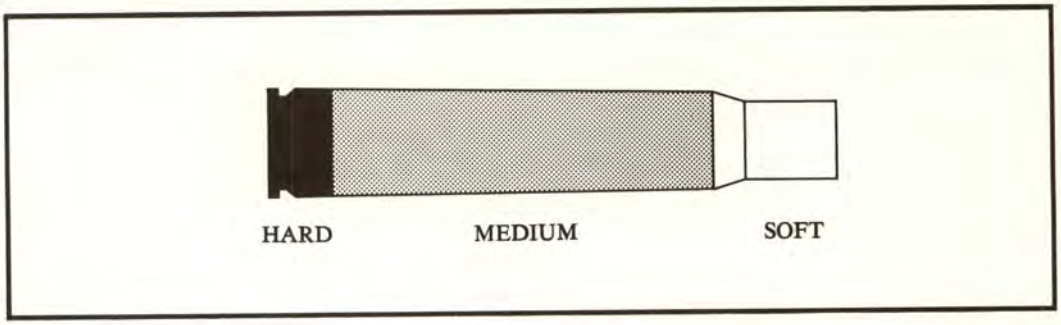
*NEVER CRIMP THESE CASES.

The reloader whose firearm is in good condition and who uses a set of quality reloading dies has little to worry about in regard to headspace. The only exception perhaps is with auto-pistol cases of the rimless straight type. As shown in the illustration, these cases headspace on the case mouth. If a crimp is used to hold the bullet in place, it may shorten the overall case length and cause excessive headspace. Poor quality reloading dies can also raise havoc with rimless bottle-neck cases. An improperly made die can move back or change the shoulder angle and drastically alter headspace. For more information on headspace, see the Pressure chapter.

Although good equipment and a little care will eliminate problems of headspace, other forces are constantly at work which effect changes in case brass. Such changes are not always obvious at a glance so the reloader must inspect his cases carefully in order to detect them.

MAXIMUM OVERALL CASE LENGTH AND TEMPER

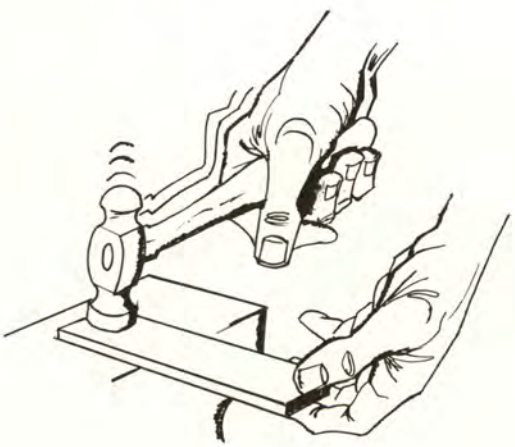
Cartridge brass is very carefully tempered in its final manufacture. Tempering leaves the neck, shoulder and body fairly soft, while the head is quite tough and hard. The obvious advantage is that the case walls will now expand freely (without cracking) to seal the chamber when the cartridge is fired. This prevents gas from escaping back between the cartridge case and the chamber wall. The head of the case remains hard so that it will resist the force that is applied to it.



Cartridge brass has the characteristic of becoming harder as it is worked. Therefore, repeated firing and resizing of a cartridge will eventually change the original tempering of the brass. The battering of chamber pressure coupled with the force applied by the resizing die will gradually work-harden the forward portion of the case and destroy its usefulness. This is called "fatigued brass" and it is recognized by cracks that begin to appear in the neck, shoulder or body of the case.

Repeated firing and sizing also affects the overall length and thickness of our cartridge brass. This combination of forces constantly pushes the case material forward, gradually thinning the side walls. More important, the neck of the case becomes longer and somewhat thicker than it was originally. As more and more of the brass is forced forward, the case neck will eventually lengthen until it exceeds the maximum tolerance allowed by the chamber. The greater thickness of the neck will tend to wedge the bullet in the chamber mouth and cause an undue increase in pressure.

A case neck which has lengthened, or thickened, excessively will sometimes show up in the bullet seating operation; the case will have a tendency to buckle when the bullet is being seated.



Brass

As brass is pounded, many of its original characteristics change. It becomes HARDER, THINNER and LONGER. The battering of chamber pressure, plus the forces applied by the resizing die affect cartridge cases in much the same manner.

To compensate for these changes which occur in the structure and length of the brass, you employ two simple operations. (1) Re-soften the case neck and shoulder by annealing them; (2) Trim off the excess material that builds up on the case neck.

How often you will need to trim, or anneal the cases, depends largely on the type of case you are using and the pressure of the load. Maximum pressure loads shorten case life tremendously. Bottle-neck cases receive more abuse from pressure than straight walled cases and require trimming more often. The trimming of any one case more than four times is not recommended. After this amount of trimming it may be assumed that the case walls are now too thin and that the neck has thickened to the point where it is raising pressure. Some pistol cases may never require trimming, but even they will eventually harden and crack from brass fatigue.

ANNEALING

Annealing is the process of altering the structure of any metal so as to make it softer and increase its ductility. A simple form of annealing will enable you to re-soften the neck and shoulder of your cases after they have become work-hardened. When a few cases show fatigue cracks, discard these few, but save the rest by annealing.

The only special equipment required for this job is a concentrated heat source, such as a propane torch, and a metal dish or pan. Fill the pan to half the case length with water and stand a cartridge case on its head in the pan of water. Heat is then applied to the neck of the case. When the neck reaches a cherry red color, quickly tip the case over into the water. The water serves as a quenching medium and leaves the neck and shoulder quite soft. It also protects the head of the case, keeping it cool so that it may retain its hardness.

TRIMMING

When the necks of your cases lengthen excessively, they must be trimmed back to a more workable overall length. A case length gauge, or vernier caliper is used to check the overall length of a cartridge case. Both of these items are described in the Accessory section of this Handbook. The Data page which lists data for your particular cartridge will supply a MAXIMUM CASE LENGTH measurement. Check your cases after resizing and never allow them to lengthen past the maximum listed measurement.

The Data page will also supply a suggested TRIM-TO-LENGTH. Several case trimmers are available (see Accessory section). These tools range from a simple device used in conjunction with a hand file, to more elaborate miniature lathes. Any one of these tools will perform the operations necessary to trim back a cartridge case.

CASE INSPECTION

In the preceding chapter on Pressure, we covered the inspection of cases after firing, and while working up a maximum load. We were then discussing new cases and signs of excess pressure. In this chapter we refer to the repeated use of cases with established

loads that have been carefully tested and found free of pressure or headspace problems. Specifically, we are talking about the wear and brass fatigue that eventually destroys the usefulness of cartridge brass.

For a thorough inspection of cases, there is a simple system. Group your cases into lots and keep a record of the number of times that you load them. This will help you to determine the case life — giving you an opportunity to extend that life when possible. If, for example, a few cases begin to show cracks from brass fatigue, you know that all the cases in that lot are in the same general condition because they have all been loaded and fired an equal number of times. You should now reject the few cases that are cracked, but save the remaining (uncracked yet) cases by annealing them. The same applies to trimming. As the cases show signs of lengthening, you can trim the entire lot and restore them to the correct overall length.

Before reloading, wipe your cases with a cloth to remove dirt and fouling. They should then be carefully inspected for fatigue cracks or splits in the neck, shoulder or body. Any cases showing these defects should be discarded. It is wise to mutilate the rejects with a pair of pliers before throwing them away. This insures against their accidental use in the future.

Your cases are now ready for reloading, but your inspection is not entirely finished. Cases should be checked after resizing to insure against fatigue cracks which might have appeared during the resizing operation. At this time they should also be checked for overall length and trimmed if needed. If trimming is necessary, trim them back to the trim-to-length shown on the Data page. Close attention while priming also weeds out any others that have stretched primer pockets. If a primer enters the pocket too easily, or seats loosely, discard the case because the primer pocket has stretched (opened) due to brass fatigue.

In conclusion, we will bring up a few matters that haven't been discussed in this chapter, but which may concern you at one time or another.

For one thing, there is the question of **Neck Resizing** as opposed to **Full Length Resizing**. In our experience, most cases show signs of fatigue first in the necks. Therefore, cases that have been full length resized give fully as much service as those that are neck resized only.

Another thing we wish to caution you against is the use of **steel cases**, or **balloon head** cases. Neither is recommended for reloading: The steel case because it is difficult to resize; the balloon head case because of its antique, weak design.

For further information on primer pockets, or Berdan primed cases, see Primer chapter. Further information on shotshell cases may be found in the Fireside Shotgunning chapter.

PRIMERS

Although a primer is responsible for only a very small percentage of the overall accuracy of the loaded round, it is, nonetheless, a very critical component.

If the primer is not properly seated, you will be constantly bothered by misfires, hangfires, or erratic ignition. Primers also have a bearing on the overall pressures in a given load.

The accompanying primer chart makes it easy to select primer sizes and styles. Never use primers for purposes for which they were not intended. While large rifle and large pistol primers have approximately the same external dimensions, they should never be interchanged. The priming compounds differ greatly, and the overall strength of the primers varies with each different size. In other words, a large rifle primer will cause higher pressures and offer more resistance to the firing pin blow than a large pistol primer will. The use of a large rifle primer in a pistol might result in a misfire or the undue raising of pressures. The use of a large pistol primer in a rifle case would result in poor ignition and possibly a pierced primer. In many cases the use of an incorrect primer will prevent flush seating of the primer.

TABLE OF PRIMER SIZES

	Large Rifle	Large Rifle Magnum	Small Rifle	Small Rifle Magnum	Large Pistol	Large Pistol Magnum	Small Pistol	Small Pistol Magnum	Shotshell "A" See Note	Shotshell "B" Below
REMINGTON & PETERS	9½	9½M*	6½ 7½**		2½		1½ 5½***		97	57 69
WINCHESTER & WESTERN	120—8½		116—6½		111-7		108—1½		209	
FEDERAL	210	215*	200		150		100		209	
ALCAN	Large Rifle MAX-FIRE		Small Rifle MAX-FIRE		Large Pistol MAX-FIRE		Small Pistol MAX-FIRE		WW209F 220 MAX-FIRE	G57F
CCI	200	250M*	400	450M	300	350M	500	550M	109	157

*For use with large rifle BELTED Magnum cases only.

**Designed for use with 221 Rem., 222 Rem., 222 Rem. Mag. & 223 Rem. cases. Contains a harder cup to prevent cratering with these hotter cartridges.

***Designed for use in 32 S & W and some 357 Mag. Revolvers—contains a softer cup to compensate for light hammer fall — necessary in some pistols which have been altered for double action shooting.

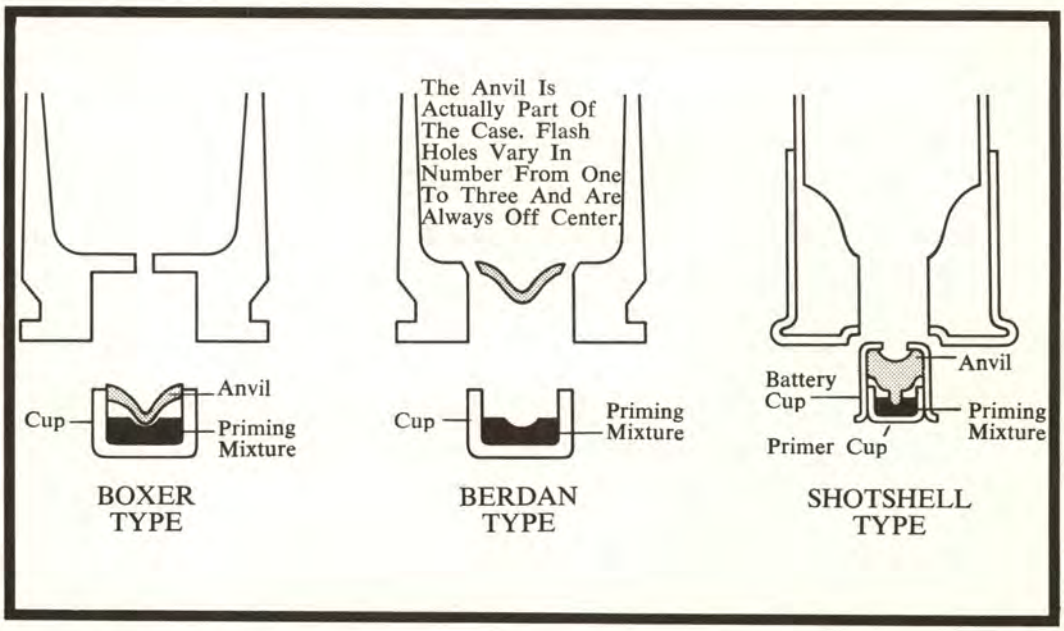
SHOTSHELL "A" — For use with Remington and Peters plastic target cases, all Winchester-Western cases, all Federal cases.

SHOTSHELL "B" — For use with Remington and Peters paper and Sp (Steel Plastic) cases.

When seating primers, make sure that the primer bottoms in the primer pocket. However, it should not be crushed. When seated, the primer should be flush with the case, or perhaps a few thousandths below the case head.

Primers with a rounded dome construction are best seated by a round priming punch, and flat primers are best seated with a flat punch. Before seating a primer, it is wise to examine it visually to make sure that the anvil is not missing. Although this rarely occurs, the resultant misfire could come at a very inopportune moment. Decapping of live primers is not recommended. If, for some reason, it must be attempted, do it slowly and carefully. Keep your hands and face away from the primer — it could ignite! To avoid a chain ignition reaction, it is also wise to move other live primers away from the area.

Basically, there are two types of primers in common use: 1. The boxer primer with its self contained anvil. 2. The Berdan primer which requires that the anvil be built into the cartridge case. The shotgun "battery cup" primer is actually a boxer primer. Because of its construction, however, the shotgun case cannot properly support a primer in a conventional manner, so the primer has a separate supporting cup into which it is placed. The illustration indicates the various types of primers.



DECAPING BERDAN PRIMERS

The Berdan is normally encountered only in cases of foreign manufacture. Because the flash hole is not centrally located in the case, the Berdan primers cannot be decapped in the normal fashion. The Berdan case usually has two flash holes slightly off center, so a decapping pin would not be able to remove the primer. The following method has been proven satisfactory for decapping Berdan primed cases.

To decap Berdan primed brass, stand the case on a block of wood which has a hole drilled through its center. This hole should be large enough to allow the primer to fall through. Then fill the case with water to the neck. A wood dowel, that just fits, is then inserted into the neck. Pressure quickly applied to the dowel will then pop the primer out. Apply the pressure by hand or with a small mallet.

Berdan primers can be seated with the aid of a regular vise. Simply start the primer by hand and then place the case in the vise and close it gently until the primer is flush with the case.

HANDLING PRIMERS

A word of caution on handling primers. Primers are detonated by percussion (a sharp blow). Therefore, they should not be tossed around. As packaged by the manufacturers, primers are quite safe to handle. But an old glass jar full of primers can become lethal if dropped.

The use of auto primer feeds has become quite common. They certainly increase the speed and convenience of producing reloads. However, if a jam or malfunction should occur with one of these devices, it should be carefully disassembled. Banging or striking the mechanism in order to free the jam could detonate the primers in the tube.

CRIMPED IN PRIMERS

Some military brass uses crimped in primers. After decapping, these cases must have the primer pocket opened up or reamed. There are various commercial tools to do this job. The Lyman primer pocket reamer, available in large and small sizes, will perform this operation quickly and inexpensively.

BULLETS

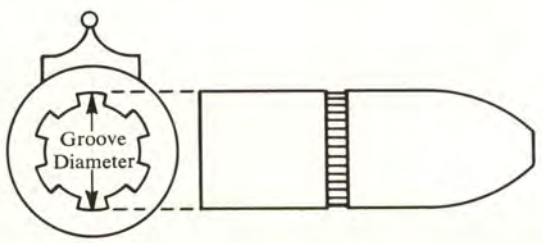
The subject of bullets is much too broad to be adequately covered in a single chapter or, for that matter, in one publication. However, bullet selection is extremely important to the reloader because the bullet is probably the single most important factor affecting load performance. Therefore, in this chapter we will present a summary on the subject of bullets which we believe will be the most helpful. We also recommend your reading of the chapters, "Accuracy With Cast Bullets," and "Accuracy With Jacketed Bullets."

When bullets are discussed, we hear about "interior" and "exterior" ballistics. Actually, these two terms refer to the ballistic conditions which exist during two distinct phases of bullet flight. "Interior" applies to the conditions which take place while the bullet is inside the rifle. "Exterior" refers to the conditions after the bullet has left the muzzle and is spinning on to the target. To choose a bullet which is safe and accurate, interior and exterior ballistics must be considered.

YOUR BULLET IN THE BARREL

First, bullets should fit exactly to the groove diameter of your rifle. If the bullet diameter is too large, it can boost chamber pressures. With hard jacketed bullets, these pressures will increase dangerously. If the bullet diameter is too small, the bullet will be highly inaccurate and inefficient. Commercial jacketed bullets when used in modern domestic firearms, seldom, if ever, create problems in bullet fit. Both firearms and projectiles are made to very close tolerances. This is not the case, however, with older guns or with guns of foreign manufacture. For example, groove diameters of the 8 x 57mm Mauser can vary from .318″ to .323″, and some imported sporters (particularly the .243's) have dangerously tight groove diameters.

Whenever there is a question of the exact groove diameter of your rifle or pistol, we suggest that you slug the bore and proceed as explained in the chapter, "Accuracy With Cast Bullets."

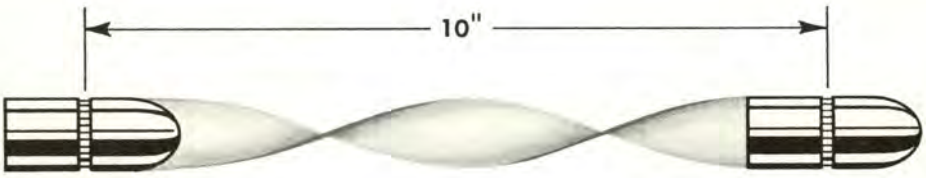


The Bullet Must Fit The Groove Diameter Of The Rifle In Which It Is Used.

The rate of twist of the rifling is directly related to the bullet weight (and velocity) which that particular rifle can handle with accuracy. Heavier and longer bullets in a given caliber require a faster rifling twist. A good example of this is the 30/06 and the .308 Winchester. Both rifles use the same diameter (.308) bullets which are available in a wide assortment of weights ranging from 110 grains up to 220 grains.

While both of these rifles turn in excellent results with all of the medium weight (150 and 180 gr.) bullets, their ability differs when it comes to the very heavy or the very light. The 30/06 will handle 220 grain bullets better because it has a faster twist of one turn in ten inches. On the other hand, the .308 Winchester turns in better results with the light 110 grain bullets due to its slower twist of one turn in twelve inches.

If very light bullets are used in a barrel with a fast twist, the bullets tend to accelerate too rapidly — jump the rifling — and deform themselves. The Data page of this Handbook which lists your cartridge, shows the rate of twist which was present in our test rifle. It also lists the bullet diameter which is standard for this cartridge. Whenever we had difficulty in obtaining accuracy with a particular bullet weight, or when we encountered wide variations in groove diameters, we made mention of it in the cartridge story which appears on the Data page.



1 IN 10 TWIST — Bullet makes one complete turn in ten inches of barrel travel.

YOUR BULLET IN FLIGHT

Once the bullet is free from the muzzle, it becomes a gyroscope. Its ability to fly on a uniform trajectory depends on its perfection of form, its balance and its rapidity of spin. Not only does the rotation of the bullet hold it to a uniform plane, it also imparts to the projectile the ability to resist other forces (wind, gravity, etc.) which strive to alter its course.

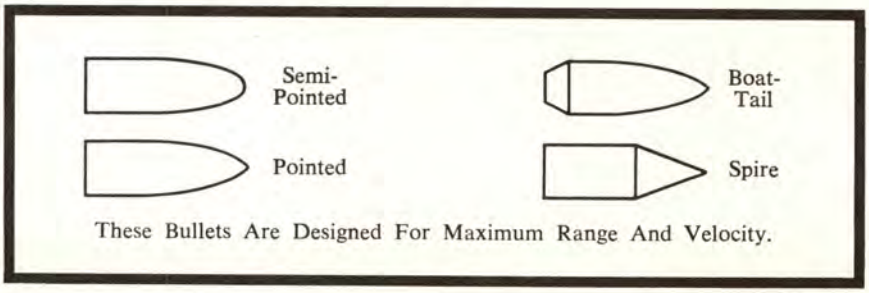
Every bullet has some minor or major imperfection which makes it different from the other bullets in its group. Even the very best bullets are never quite perfect gyroscopes and this shows up in the size of the groups which we fire. When we use care and select bullets for their uniformity of weight, etc., we are usually rewarded by smaller groups and better scores. On the other extreme, if we're careless in handling our bullets by deforming them in the magazine, or shooting them through a poor bore, then results are noticeably poor.

The shape and weight of the bullet affects its ability to perform at any given range. Heavier bullets (as opposed to light bullets of the same caliber) tend to better conserve their forward velocity and rotational spin. For this reason, a heavier bullet will have a longer extreme range, and deliver a higher percentage of its original energy to the target. Light

bullets (as opposed to heavy bullets of the same caliber) can be driven at higher velocities and consequently give flatter trajectories, but have a shorter usable range. The lighter bullet is also more affected by the forces of the wind.

The nose shape (ogive) of the bullet indicates the purpose for which it is designed. Sharp pointed bullets overcome the resistance of air and conserve their remaining velocity much better than blunt nose bullets. Pointed bullets (as opposed to blunt bullets of the same weight and caliber) will give flatter trajectories and a longer range potential. This ballistic superiority of the pointed bullet is not appreciably noticeable at ranges under 200 yards.

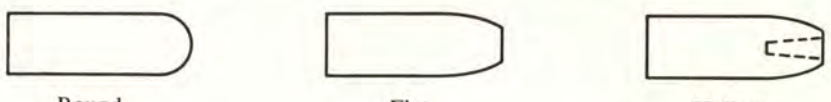
Another long range bullet is the boat-tail design. The base of this bullet is tapered at an angle of about nine degrees. The purpose of the taper is to reduce drag caused by a vacuum at the base of the bullet. This feature helps the bullet to conserve its remaining velocity. A bullet of the boat-tail design has no short range advantage. Its superiority starts to show up at ranges of about 600 yards, or after the bullet's remaining velocity has been reduced to about the speed of sound (1100 F.P.S.).



These Bullets Are Designed For Maximum Range And Velocity.

Naturally, maximum range and maximum velocity are not always required of a bullet. There are times, in fact, when sharp pointed bullets present definite disadvantages which offset their long range superiority. In a tubular magazine rifle, for instance, the use of a pointed bullet is actually dangerous because the point of one bullet rests against the primer of another cartridge. Under such conditions, a pointed bullet could accidentally chain fire the magazine when the rifle was under recoil.

Many very fine blunt nose bullets are available to the reloader particularly in the larger calibers. These bullets are designed almost exclusively for hunting. Their "controlled expansion" features better suit them for game loads. At the short-to-medium ranges (up to about 200 yards) for which these bullets are designed, they are usually just as accurate as the pointed type.



Bullets Of These Types Are Designed Primarily For Hunting.

PENETRATION AND EXPANSION

A target shooter can easily justify any bullet weight, or design, which gives him his best shooting load. The hunter must go one step further. Hunting requires a bullet which will "go to work" after it strikes the target — **it must kill clean**. Putting together good hunting loads is not always easy and sometimes we make concessions in accuracy in order to use a particularly good bullet weight or design.

On big game, the bullet must possess the ability to drive deeply into the vital area of a large animal **and stop there**, delivering its total remaining energy to the body tissue. If the bullet is too heavy, or too hard, it will penetrate completely through the animal's body and defeat our purpose by allowing much of the bullet's energy to escape with the bullet. If, on the other hand, it is too light, or too soft, the bullet may never reach a vital area and break apart when it strikes a shoulder or rib.

In cartridges that are intended for varmint hunting, fast, light bullets are used. Such bullets have very thin jackets and are designed to virtually blow up on contact and expand their total energy on the small body area of varmints such as woodchucks or crows. Not only are these fast little projectiles excellent for the purpose for which they are designed, but their explosive characteristics limit the danger of ricochet.

Ammunition companies and manufacturers of jacketed bullets have vast experience in this area of bullet expansion. Exhaustive testing and field research have produced the reliable jacketed bullet design which they offer for sale. We recommend that you follow their advice when choosing a bullet for a particular game animal. Your experience, however, is still an essential factor because only by a certain amount of trial and error on your part can you develop truly good hunting loads. Try several different brands of the same bullet weight and style before making up your mind on a load. Bullet construction and jacket thickness can vary considerably from brand to brand.

CAST LEAD ALLOY BULLETS

In selecting bullets for various purposes, do not overlook the benefits which can be had from cast bullet shooting. First, there is this business of economy. A reloader can turn out a good cast bullet for a fraction of the cost of its jacketed counterpart. Ten pounds of bullet metal, for example, makes over twelve hundred (55 gr.) bullets which is a good bit of shooting for anyone's money. Aside from the outright savings involved, the cast bullet is a proven performer which plays an important part in today's reloading picture.

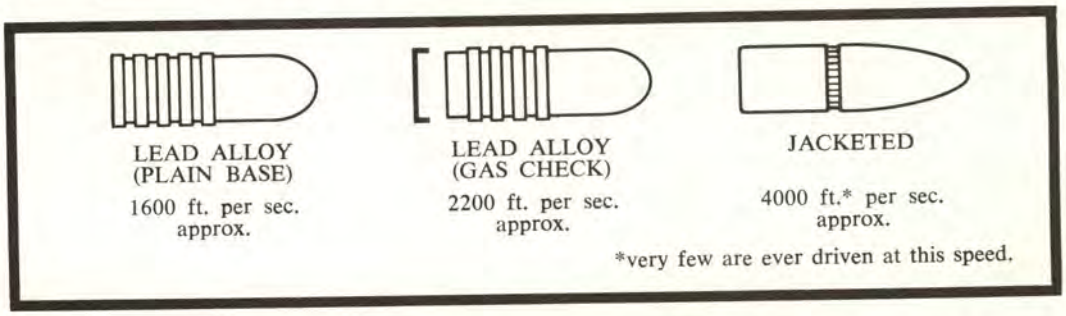
Not only is the cast bullet still at the top of the list as the number one handgun bullet, it is steadily regaining importance to the rifle shooter. Cast bullets lend themselves better to low velocity (light recoil) shooting than do jacketed bullets. While this may not sound like a great advantage, consider, if you will, the hundreds of letters that we receive each year from satisfied users of cast bullets. These shooters have gone beyond the heavy load, heavy recoil, loud noise stage. Instead, they have found that about 95% of their shooting can be done more accurately, more comfortably, and more economically with cast bullet loads. Many letters are from shooters who, using a particularly super accurate cast bullet reload, have won 100 and 200 yard rifle matches against shooters using the finest jacketed bullets available.

Another advantage of the cast alloy bullet is added barrel life. Cast bullets (due to the shorter burning time of the charge) extend indefinitely the accuracy life of your barrel. It's true, of course, that in a rifle such as a 30/06, the alloy bullet cannot be driven at the peak velocity of the rifle and cartridge. At 200 yards, however, bullet #311291 (#2 alloy) can give many 06 users a real surprise in what optimum accuracy means. In preparing accuracy loads for this Handbook, a great many of our cast bullet groups were actually half the size of those turned in with jacketed bullets in the same rifle.

In some rifles, (30/30, 32 Win. Spec., 35 Rem., etc.) the alloy bullet can be used at a speed which actually equals the rifle's velocity capability. Throughout this Handbook we have listed recommended data to be used with cast alloy bullets. We have also suggested bullet numbers which we feel will turn in the best results with this data. If you are a handloader who would like to experience the thrill of superior performance and at the same time save money, then don't overlook the cast alloy bullet.

CAST BULLET METAL AND VELOCITY

The speed at which a bullet can be driven depends largely upon the hardness of the bullet itself. If the bullet material is too soft, the bullet will deform itself in the bore and become highly inaccurate in flight. It would be, in fact, a very poor substitute for the perfect gyroscope which we mentioned earlier in this chapter. The toughness of a jacketed bullet allows it to be driven at very high velocities (over 4000 F.P.S. in some instances and with some bullets). The cast bullet never equals the jacketed bullet's hardness and, consequently, it must be held to the more moderate velocity of approximately 2200 F.P.S.

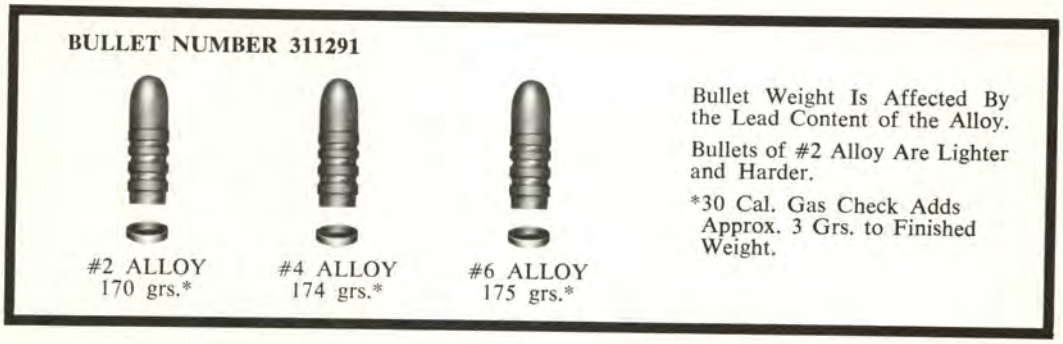


The foregoing illustration shows an approximate working velocity comparison between jacketed and cast bullets. The cast bullet velocities shown can only be reached with hard bullets of #2 alloy. The gas check (shown near center bullet) is made of gilding metal. These small cups slip over the bullet base to protect it from hot powder gases and to permit higher velocities.

Over the years Lyman has offered three different lead alloy materials for bullet making use. These alloys vary in their composition and are identified as: #2 alloy, #4 alloy, and #6 alloy. Number 2 alloy is the hardest of these three materials (others do not contain antimony) and it is recommended for all cast bullet rifle and pistol loads shown in this Handbook. Only pure lead should be used for rifled slugs and muzzle loading bullets.

#2 ALLOY { 90 parts lead
5 parts tin
5 parts antimony

The antimony in #2 alloy is used to harden the bullet. The mixture, however, must also contain tin. The reason for this is that while antimony mixes with lead in the molten state, it will not remain mixed when it solidifies. If tin were not added, we would have pure antimony crystals surrounded by pure lead. A bullet of this type while it feels hard, would certainly lead the bore. In a lead-tin-antimony mixture, the antimony crystals will be present just the same, but they will be imbedded in a lead-tin mixture.



The foregoing illustration shows how the lead content of the alloy affects the weight of the finished bullet. This picture features the same bullet cast from three different alloys. The cast bullet weights shown for rifle and pistol data in this Handbook represent bullets cast from #2 alloy only.

MIXING YOUR OWN #2 ALLOY

Making your own bullet alloy is really quite easy. A mixture that compares very favorably to Lyman #2 alloy may be concocted by melting down a few items which are readily available. Some of these items contain small traces of other metals, but from the standpoint of making bullets they may be considered as pure.

5½ lbs. wheelweights
1 lb. 50/50 bar solder
3½ lbs. lead
} Makes 10 lbs. #2 alloy

4 lbs. Line-O-Type
1 lb. 50/50 bar solder
5 lbs. lead
} Makes 10 lbs. #2 alloy

Wheelweights contain about 9% antimony and they are available at most any gas station or automotive supply. Bar solder which contains 50% tin and 50% lead is available from plumbing and hardware stores. Line-O-Type which contains 12% antimony, 4% tin, and 84% lead, can often be purchased from a local printer. Pure lead may be found at a junk yard in pipe form, or it can be purchased in ingot form from a local plumber.

WHY CAST BULLETS MUST BE SIZED

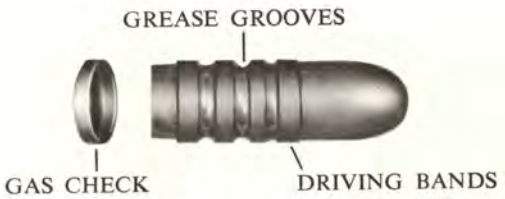
When lead alloys solidify they also shrink in size. The more lead content to the alloy, the more this shrinkage is noticeable. Depending upon the type of alloy used, and the heat of the mould and mixture, this shrinkage could be as much as .003". Our freshly cast bullet is, therefore, somewhat smaller than the mould cavity in which it was cast.

As our bullets must fit the groove diameter of the rifle, we, then, size them down to an exact standard diameter. The cavity in a bullet mould is made large enough to compensate for this shrinkage and resizing. For example, most 30 caliber moulds produce bullets of approximately .311" diameter which leaves enough metal (even after it shrinks) so that the bullets can be sized to the standard .308" groove diameter of the rifle.

The bullet sizing dies (G, H & I) which Lyman offers for sale, **do not cut away bullet metal** to reduce and standardize the bullet diameter. These dies **actually swage** bullets into perfect round projectiles which have a standard and consistent diameter. Sizing a bullet in these dies does not alter the bullet's cast weight as no metal is removed.

The versatility permitted by sizing bullets is a real benefit to the shooter who owns a rifle which has a non-standard groove diameter. By casting and sizing his own bullets, the shooter has the opportunity of fitting them exactly to his rifle's dimensions. For example, if a particular 30/06 has an oversize .309" groove diameter, he can resize to this diameter and obtain a perfect bullet fit (see "Accuracy With Cast Bullets" in this section).

When a cast bullet is pushed into a sizing die it is lubricated at the same time and a gas check is seated. A special bullet grease (Lyman bullet lubricant) is forced into the grease grooves which are designed into the bullet. The use of this lubricant increases accuracy and eliminates barrel leading if the correct bullet metal and velocities are adhered to.



The foregoing illustration shows a typical cast bullet design. The bullet pictured is one designed for use with a gas check (note base). A bullet of this type may be used with, or without, the gas check provided the proper velocities are adhered to. Many cast bullets are designed with plain bases (not for use with gas check). These bullets must be restricted to their lower velocity level.

HOLLOW POINTS

When a cast bullet is to be used on game animals, we recommend the use of a hollow point bullet. All Lyman bullet designs (with the exception of hollow base bullets) are available in hollow point design. To order these moulds, the shooter need only to specify the bullet number he wishes and write H.P. after the number. Because of their construction, hollow point moulds are available in single cavity only. While hollow point bullets are lighter in weight than conventional bullets of the same number, the reloader may feel free to use conventional cast bullet data.

For more information on cast bullets see the "Accuracy With Cast Bullets" chapter in this section of your Handbook.

The remainder of this chapter is devoted to a listing of the various bullets which were used in collecting data for this Handbook. While this is not a complete list of all the bullets which are available to the handloader, you will none the less find it useful in selecting a bullet for your load. Where possible we have added notes and suggestions which we felt would be helpful.

ALL BULLETS ARE PICTURED ACTUAL SIZE

JACKETED RIFLE BULLETS

.22 CALIBER (.224 Dia.)

40 GRAINS

Pictured is a Speer soft point which is designed primarily for such cartridges as the 22 Hornet and 218 Bee. A similar bullet is also available from Sierra.

45 GRAINS

The bullet pictured is a Remington Hollow Point. Bullets of the same caliber and weight but with various nose designs (soft point, semi-pointed, etc.) are also available from Hornady, Speer, Sierra and Winchester. While this weight bullet is normally used in 22 Hornet and 218 Bee cartridges, a high velocity version (having a tougher jacket) is available for cartridges producing 3000 F.P.S. or more.

50 GRAINS

The bullet pictured is a Remington Soft Point. Bullets of the same caliber and weight but with various nose designs (pointed soft point, Spitzer, Semi-pointed, Full-Jacket, Spire, etc.) are available from Hornady, Speer, Norma, Sierra and Winchester. These bullets are basically for velocities in excess of 3000 F.P.S. A thinner jacketed version offered by both Hornady (SX) and Sierra (Blitz) is designed for 222 type cartridges.

52 GRAINS

The bullet pictured here is a Speer Hollow Point. A Sierra 53 grain bullet is also available and may be used interchangeably with the 52 grain bullet data listed in this Handbook.

55 GRAINS

The bullet pictured is a Remington Soft Point. Bullets of the same caliber and weight but with various nose designs (Pointed Soft Point, Semi-pointed, Spitzer, Full Metal case, Spire, etc.) are available from Hornady, Remington, Speer, Norma, Sierra and Winchester. A thinner jacketed version offered by both Hornady (SX) and Sierra (Blitz) is designed for 222 type cartridges.

63 GRAINS

Pictured is a Sierra Semi-Pointed bullet. This is an excellent bullet for the hotter 22 calibers such as the 220 Swift or the 22-250.

.243 CALIBER & 6mm (.243 Dia.)

60 GRAINS

The bullet pictured is a Sierra Hollow Point. This is a light bullet which is best suited for ranges under 200 yards and small varmint.

70 GRAINS

The bullet shown here is a Hornady Hollow Point. This is a light bullet and is best suited for ranges under 200 yards and small varmint.

75 GRAINS

Pictured is a Remington Pointed Soft Point. Bullets of this same caliber and weight are also available from Hornady, Speer, Norma and Sierra. Nose shapes include Hollow Point and Spire. This is an excellent weight bullet for all types of varmint shooting.

80 GRAINS

Pictured is a Remington Pointed Soft Point. Bullets of this same weight and caliber are also available from Speer and Winchester. Other nose shapes include the Hollow point design.

85 GRAINS

The bullet pictured is a Sierra Spitzer. This bullet is exceptionally good for very long range varmint shooting.

90 GRAINS

The bullet pictured is a Remington Soft Point, but similar bullets are also available from Speer and Norma. Available nose shapes include the Spitzer design. A bullet of this weight is an excellent choice for deer and like game.

100 GRAINS

The bullet pictured is a Remington Pointed Soft Point. Bullets of this same weight and caliber but with other nose designs (Soft Point, Spitzer, Semi-Pointed, Full Jacket, Spire, etc.) are available from Hornady, Norma, Sierra and Winchester.

.25 CALIBER (.257 Dia.)

60 GRAINS

Pictured here is a Remington Hollow Point. Bullets of this same weight and caliber but having various nose designs (Spire, etc.) are also available from Hornady, Speer and Winchester. Remington and Winchester bullets are designed for 25/20 and .256 Win. velocities. Bullets from other makes are designed for velocities of 3000 F.P.S. and faster.

75 GRAINS

Pictured here is the Sierra Hollow Bullet. A similar bullet is also available from Hornady. Either bullet is an excellent choice for varmint shooting.

86 GRAINS

The bullet pictured is a Remington Soft Point which is designed primarily for 25/20 velocities. This bullet can be used successfully in the .256 Winchester.

87 GRAINS

The bullet pictured here is the Remington Soft Point. Bullets of this same weight and caliber but having various nose designs (pointed soft point, Spire, Spitzer, etc.) are also available from Hornady, Speer, Norma, Sierra and Winchester. This is usually the best 25 cal. bullet weight for long range varmint shooting.

100 GRAINS

Pictured here is a Remington Pointed Soft Point. Bullets of the same weight and caliber but having various nose designs (Spitzer, Soft Point, Spire, etc.) are also available from Hornady, Speer, Norma, Sierra and Winchester. Bullets of this weight are a good choice for deer, antelope, etc.

117 GRAINS

Pictured is a Remington Soft Point. Similar bullets are also available from Hornady, Sierra and Winchester. Nose shapes include Round Nose and Spitzer. Boat-tail bullets are also available for 1000 yard target shooting. Bullets of this weight afford maximum penetration for this caliber.

.264 CALIBER & 6.5mm (.264 Dia.)

85 GRAINS

Pictured is a Sierra Hollow Point. This is a good short range varmint bullet which is best suited for velocities of under 3200 F.P.S.

100 GRAINS

The bullet pictured is a Remington Pointed Soft Point, but similar bullets are also available from Hornady, Sierra and Winchester. Nose designs include Spire and Hollow point. An excellent long range varmint bullet.

120 GRAINS

The bullet pictured is a Sierra Spitzer, but similar bullets are also available from Remington and Speer. This is a good bullet for deer and antelope.

129 GRAINS

The bullet pictured is a Hornady Spire Point which is an excellent bullet for medium sized game.

140 GRAINS

The bullet pictured is a Remington Pointed Soft Point. Similar bullets with Round or Spitzer nose design are available from Winchester, Hornady, Speer and Sierra. The Sierra version with boat-tail is excellent for 1000 yard target shooting. Bullets of this weight are designed primarily for the larger 6.5 cases such as the .264 Magnum.

160 GRAINS

The bullet pictured is a Hornady Round Nose. This bullet is designed primarily for the medium and small capacity 6.5 cases (as 6.5 Mann. Schoe. and 6.5 x 55).

.270 CALIBER (.277 Dia.)

90 GRAINS

The bullet pictured is a Sierra Hollow Point. This bullet is a good selection for short to medium range varmint shooting.

100 GRAINS

The bullet pictured is a Remington Pointed Soft Point. Bullets of the same weight but with varying nose designs are also available from Hornaby, Speer and Winchester. Bullets of this weight are excellent for long range varmint shooting.

130 GRAINS

The bullet pictured is a Remington Pointed Soft Point. Bullets of this same weight are also available from Hornady, Speer, Norma, Sierra and Winchester. Nose shapes will vary with brand, but they include Hollow Point, Soft Point, Spitzer, Full Jacket and Spire. Also available are boat-tail designs. An excellent weight hunting bullet for deer and similar game.

150 GRAINS

Pictured here is the Remington Soft Point. Bullets of this same weight but with various nose designs are also available from Hornady, Speer, Norma, Sierra and Winchester. Nose selection includes Spitzer, Full Jacket, Spire and Round Nose. With the proper nose this bullet is good for big game at ranges up to 200 yards.

170 GRAINS

Pictured here is a Speer Soft Point. This bullet is best suited for Magnum cases and is usable where maximum penetration is required.

.284 CALIBER & 7mm (.284 Dia.)

120 GRAINS

Pictured is a Sierra Spitzer which is a good varmint bullet for 7 M/M cases. A similar bullet is also available from Hornady as a Spire Point.

139 GRAINS

Pictured is a Hornady Spire Point. An excellent choice for long range shooting.

150 GRAINS

Pictured is the Remington Pointed Soft Point. Bullets of this weight but having various nose designs (Soft Point and Full Jacket) are also available from Norma and Winchester. Remington offers this bullet with a heavier than normal jacket for use in magnum cartridges.

165 GRAINS

Pictured is a Remington Soft Point. A big game bullet for medium range.

175 GRAINS

Pictured is the Remington Soft Point. Similar bullets of the same weight are also available from Hornady, Norma and Winchester. Remington offers a special version with a heavy jacket for use in Magnum cases.

7.35mm (.298 & .300 Dia.)

128 GRAINS

Pictured is the Hornady Spire Point which has a diameter of .300″. This bullet is for use in the 7.35 M/M Italian, and may be used in rifles having a .300″ or .301″ groove.

150 GRAINS

Pictured is the Speer Soft Point. This bullet has a diameter of .298″ and may be used in rifles having a .298″ or .299″ groove.

.30 CALIBER (.308 Dia.)

110 GRAINS

Pictured is a Remington Pointed Soft Point. In various nose shapes (Round Nose, Hollow Point, Full Jacket, Spire, etc.) bullets of this same weight are available from Hornaby, Remington, Speer, Norma, Sierra, and Winchester. While these bullets are basically designed for varmints, round nose versions seem best suited for moderate velocity cartridges such as the 30M1 Carbine and 30/30.

125 GRAINS

Pictured is a Remington Pointed Soft Point. Bullets of this same weight are also available from Sierra and Winchester. While these bullets are designed for long range varmint shooting, they are also excellent target bullets for 300 yards. This weight bullet may be used with the 130 grain bullet data listed in this Handbook.

130 GRAINS

Pictured is a Hornady Spire Point. Bullets of this same weight are also available from Speer and Norma. Nose styles include Full Jacket and Semi-Pointed designs. Some are available with boat-tail. This bullet has the same application as the 125 grain weight.

150 GRAINS

Pictured is a Remington Soft Point. This is one of the most popular thirty caliber bullet weights and is therefore available from most every bullet maker. Bullets of this weight can be had in most any nose design, but due to the multiple purpose of this bullet weight, many specialty designs exist. Some bullets are designed for 30/30 velocities, while others are designed for the velocities of the 30/06 and still others are intended for magnum speeds. It is important that you select a bullet which is designed for your application.

165 GRAINS

Pictured here is a Speer Spitzer. Bullets of this weight are becoming popular as thirty caliber target bullets. Both Hornady and Sierra offer match bullets of 168 grain which may be used with the data listed for the 165 grain bullet in this Handbook. If this substitution is made, however, reduce the maximum charge one full grain.

170 GRAINS

Pictured is a Remington Hollow Point. Bullets of this same weight are available in either flat or Round Nose from most every manufacturer. These bullets are designed specifically for 30/30 velocities.

180 GRAINS

Pictured here is a Remington Soft Point. This thirty caliber bullet competes in popularity with the 150 grain weight and again is available from most every bullet maker. A wide selection of nose designs are offered. The 180 grain weight is an excellent thirty caliber hunting bullet for all but the largest of big game.

200 GRAINS

Pictured is the Speer Soft Point. Hunting bullets of this weight are also available from Winchester and Remington. Sierra makes a very excellent target bullet of this same weight. The 200 grain bullet offers maximum penetration for rifles such as the .308 which will not stabilize the heavier thirty caliber bullets.

220 GRAINS

Pictured is the Remington Soft Point. Similar bullets of this weight are also available from Hornady, Sierra and Winchester. In thirty caliber rifles which will handle this bullet weight, it is an excellent choice for maximum penetration on very large game.

.32/20 CALIBER (.310 Dia.)

80 GRAINS

Pictured is a Remington Hollow Point. This bullet is designed primarily for use in the 32/20 Winchester cartridge.

100 GRAINS

Pictured is a Remington Soft Point. This bullet is designed primarily for use in the 32/20 Winchester cartridge.

.303 CALIBER & 7.7mm (.311 to .313 Dia.)

150 GRAINS

Pictured is the Speer Soft Point. A similar bullet is also available from Hornady, Norma and Sierra. Nose shapes include Spitzers and Spire.

180 GRAINS

Pictured is a Remington Soft Point. Bullets of this weight are also available from Speer, Sierra and Winchester. A good bullet for maximum penetration in this caliber.

215 GRAINS

Pictured is a Remington Soft Point. This bullet despite its heavy weight, is not designed for extreme penetration. Due to its nose shape and jacket thickness it works well on deer and black bear.

.32 CALIBER (.319 to .321 Dia.)

170 GRAINS

Pictured is a Remington Hollow Point. Similar bullets are also available from Winchester, Hornady and Speer. Nose shapes include Round Nose and Flat Point. These bullets are designed primarily for 32 Win. Special velocities.

8mm (.322 to .323 Dia.)

125 GRAINS

Pictured is a Speer Spire Point. This bullet is designed primarily as a varmint bullet for the 8 x 57 M/M Mauser.

150 GRAINS

Pictured is the Speer Soft Point. Similar bullets are also available from Hornady and Sierra. Nose shapes include Spitzers and Spire Points.

170 GRAINS

Pictured is a Remington Soft Point. Similar bullets are also available from Hornady and Speer in Round Nose and Semi-Spitzer design. Round nose designs are an excellent choice for deer and black bear.

225 GRAINS

Pictured is the Speer Soft Point. This bullet is excellent where maximum penetration is desired.

.338 CALIBER (.338 Dia.)

200 GRAINS

Pictured is a Speer Soft Point. Bullets of this weight are also available from Hornady and Winchester. In the big magnum cartridges these bullets work well for long range shooting and thin skinned game.

225 GRAINS

Pictured is the Hornady Spire Point. The application of this bullet is basically the same as that of the 200 grain.

250 GRAINS

Pictured here is a Hornady Round Nose. This bullet weight is also available from Winchester in a silvertip design. The bullet is an excellent choice for all but the largest of big game.

275 GRAINS

Pictured here is a Speer Soft Point. A bullet of this same weight is also available from Hornady in a Round Nose design. These bullets are designed for maximum penetration and may be used on very large game such as grizzly and brown bear.

.348 CALIBER (.348 & .349 Dia.)

200 GRAINS

Pictured is a Remington Soft Point. This bullet weight is also available from Hornady in a Flat Point design.

220 GRAINS

Pictured is the Speer Soft Point. This bullet is designed for maximum penetration.

.351 CALIBER (.351 Dia.)

180 GRAINS

Pictured is the Remington Soft Point. This bullet is designed expressly for the Winchester .351 Self-Loader.

.35 CALIBER (.358 Dia.)

150 GRAINS

Pictured here is a Remington Pointed Soft Point. This bullet is designed for thin skinned game at moderate ranges. As it is a pointed bullet, it should not be used in rifles with tubular magazines.

200 GRAINS

Pictured is a Remington Soft Point. Similar bullets are available from Winchester, Norma and Hornady. Nose designs include Round Nose and Hollow Point. Pointed Soft Points are also available with heavier jackets for use in cartridges which have a higher velocity than the 35 Remington. In the 35 Remington, use the thinner jacketed bullets to insure positive expansion.

250 GRAINS

Pictured is a Remington Pointed Soft Point. Similar bullets are also available from Hornady, Speer, Norma and Winchester. Bullets of this weight are designed for cartridges which are in the ballistic class of the .358 Winchester. An excellent bullet weight for large game.

275 GRAINS

Pictured is a Hornady Round Nose. These bullets are primarily for use in magnum type cases when maximum penetration is desired.

.375 CALIBER (.375 Dia.)

235 GRAINS

Pictured is the Speer Soft Point. This is an excellent weight bullet for long range shooting on thin skinned game.

270 GRAINS

Pictured is a Remington Soft Point. Similar bullets of this weight are also available from Hornady and Winchester. The bullet weight is excellent for long range use and Round Nose versions work well on large game.

285 GRAINS

Pictured is a Speer Soft Point. This bullet is similar in performance to the 270 grain except that it is not as well suited for extreme ranges.

300 GRAINS

Pictured is a Hornady Round Nose. Similar bullets of this weight are also available from Remington and Winchester. A good bullet weight for moderate ranges when maximum penetration is desired.

.38 CALIBER (.376 Dia.)

255 GRAINS

Pictured is a Remington Soft Point, but a similar bullet is also available from Winchester. Both bullets are designed for the 38/55 Winchester cartridge.

.38/40 CALIBER (.400 Dia.)

180 GRAINS

Pictured is a Remington Soft Point, but a similar bullet is also available from Winchester. These bullets are designed for use in the 38/40 cartridge and may be used in either rifles or handguns which are chambered for this cartridge.

.44 CALIBER (.425 to .427 Dia.)

200 GRAINS

Pictured is a Remington Soft Point, but a similar bullet is also available from Winchester. These bullets are designed for use in the 44/40 cartridge and may be used in either rifles or handguns which are chambered for this cartridge.

.44 CALIBER (.429 to .431 Dia.)

225 GRAINS

Pictured is a Speer Half Jacketed Bullet. This bullet is designed for use in the 44 Magnum cartridge and may be used in either rifles or handguns which are chambered for this cartridge.

240 GRAINS

Pictured is a Remington Soft Point. A bullet of this weight is also available from Winchester in a Hollow Point design. These are the most desirable jacketed bullets for the 44 Magnum cartridge. They may be used in either rifle or pistol.

.45 CALIBER (.457 Dia.)

300 GRAINS

Pictured is a Hornady short jacket bullet. Suitable for deer at short range.

405 GRAINS

Pictured is a Remington Soft Point. A similar bullet is also available from Winchester. This is the standard jacketed bullet for the 45/70 cartridge. It may also be used on thin skinned game in the .458 cartridge.

500 GRAINS

Pictured is a Remington Full Patch. Bullets of this weight are also available from Winchester. They are intended for very large game such as brown bear, tiger, etc.

The bullet weights and dimensions listed here represent bullets cast from our number two alloy. Variations in blending the alloy, casting procedure and mould tolerance could lead to minor changes in these specifications.

The bullet weights listed are less gas checks. The average weight of Lyman gas checks are as follows:

.22 cal.	.75 grs.	.338 cal.	2.0 grs.
.243 cal. (6mm)	1.5 grs.	.348 cal.	4.5 grs.
.25 cal.	1.5 grs.	.35 cal. (.38 spec. & .357 cal.)	2.5 grs.
.264 cal. (6.5mm)	2.0 grs.	.375 cal.	3.5 grs.
.270 cal.	3.0 grs.	.41 cal.	5.0 grs.
.284 cal. (7mm)	4.5 grs.	.44 cal.	5.0 grs.
.30 cal. (.308 to .313)	3.0 grs.	.45 cal.	7.0 grs.
.32 cal. (8mm)	3.0 grs.		

ALL BULLETS ARE PICTURED ACTUAL SIZE

CAST LEAD ALLOY RIFLE BULLETS

.22 CALIBER (.224 Dia.)

37 GRAINS

Bullet #225107 — This bullet is designed for use with a gas check. It has one groove and a normal cast diameter of .226. It is best suited for use in the smaller 22 caliber cases.

44 GRAINS

Bullet #225438 — This bullet is designed for use with a gas check. It has three grooves and a normal cast diameter of .227. It is best suited for cases up to the .222 Remington Magnum.

49 GRAINS

Bullet #225415 — This bullet is designed for use with a gas check. It has two grooves and a normal cast diameter of .228. A accurate bullet in all 22 caliber cases.

57 GRAINS

Bullet #225462 — This Loverin design bullet is intended for use with a gas check. It has three grooves and a normal cast diameter of .226. It is best suited for use in the .222 Magnum or larger cases.

.22 CALIBER (.228 Dia.)

59 GRAINS

Bullet #228365 — Designed for use with a gas check, this bullet is best suited for the 22 Savage Hi-Power cartridge. It has three grooves and a normal cast diameter of .229.

78 GRAINS

Bullet #22835 — This plain base bullet has eight grooves and a normal cast diameter of .232. It is an excellent bullet for the 22 Savage Hi-Power.

.243 CALIBER & 6mm (.243 Dia.)

60 GRAINS

Bullet #244203 — This is a plain base bullet with three grooves and has a normal cast diameter of .248.

84 GRAINS

Bullet #245496 — A gas check, Loverin design bullet having five grooves and a normal cast diameter of .246. An excellent bullet for .243 and .244 cases.

93 GRAINS

Bullet #245497 — A gas check, Loverin design bullet having six grooves and a normal cast diameter of .247. A good bullet for .243 and .244 cases.

99 GRAINS

Bullet #245498 — A gas check, three groove bullet which has a normal cast diameter of .246. This bullet will not stabilize well in many of the 6mm rifles.

115 GRAINS

Bullet #244253 — A plain base eleven groove bullet which was originally designed for the Lee-Navy cartridge. It is difficult to obtain accuracy with this bullet in present day 6mm rifles.

.25 CALIBER (.257 Dia.)

67 GRAINS

Bullet #257420 — A gas check, two groove bullet which has a normal cast diameter of .259.

74 GRAINS

Bullet #257463 — A gas check, four groove bullet of Loverin design which has a normal cast diameter of .260. The bullet is usually very accurate.

89 GRAINS

Bullet #257312 — A gas check, three groove bullet which has a normal cast diameter of .259. This bullet is excellent for 25/20 and similar cartridges.

89 GRAINS

Bullet #257464 — A gas check bullet of Loverin design which has five grooves and a normal cast diameter of .260. This is an excellent bullet for most all of the 25 caliber rifles.

98 GRAINS

Bullet #257418 — A gas check bullet which has two grooves and a normal cast diameter of .258. It is a bit more difficult to obtain accuracy with this bullet than with those previously listed for the 25 caliber.

113 GRAINS

Bullet #257325 — A gas check, three groove bullet which has a normal cast diameter of .260. This is a good performer in 25/35 and 25 Remington cartridges.

.264 CALIBER & 6.5mm (.264 Dia.)

101 GRAINS

Bullet #266305 — A gas check, one groove bullet which has a normal cast diameter of .266.

119 GRAINS

Bullet #266324 — A plain base, two groove bullet which has a normal cast diameter of .268. This bullet was originally designed for the 6.5 Mann. Schoe. It is an excellent bullet for all 6.5 cases provided it is used at moderate velocity (under 1650 F.P.S.).

127 GRAINS

Bullet #266455 — A gas check, seven groove bullet of Loverin design which has a normal cast diameter of .267. This is an excellent bullet for all 6.5 cases and is usually very accurate.

141 GRAINS

Bullet #266469 — A gas check bullet of Loverin design which has six grooves and a normal cast diameter of .267. This is an excellent bullet for all 6.5 cases.

.270 CALIBER (.277 Dia.)

114 GRAINS

Bullet #280468 — A gas check bullet of Loverin design which has six grooves and a normal cast diameter of .283. A very accurate bullet.

125 GRAINS

Bullet #280473 — A gas check bullet having two grooves and a normal cast diameter of .282.

136 GRAINS

Bullet #280412 — A gas check bullet having two grooves and a normal cast diameter of .284. It is an excellent bullet for all .270 caliber cases.

.284 CALIBER & 7mm (.284 Dia.)

118 GRAINS

Bullet #287448 — A gas check bullet which has four grooves and a normal cast diameter of .288. This is an excellent bullet for the 7 x 57 Mauser and other 7mm cases.

135 GRAINS

Bullet #287346 — A gas check bullet having three grooves and a normal cast diameter of .288. A good bullet for most all of the 7mm's.

150 GRAINS

Bullet #287405 — A gas check bullet of Loverin design which has eight grooves and a normal cast diameter of .288. A very accurate bullet for all 7mm cases.

164 GRAINS

Bullet #287308 — A gas check bullet having two grooves and a normal cast diameter of .289. This bullet was originally designed for the .280 Remington but it works well in all 7mm cases.

175 GRAINS

Bullet #287221 — A plain base bullet having nine grooves and a normal cast diameter of .286. This bullet was originally designed for the 28/30/120 Stevens, but it works well in the 7mm's when a very heavy bullet is desired.

7.35mm (.299 to .301 Dia.)

146 GRAINS

Bullet #300136 — A gas check bullet having two grooves and a normal cast diameter of .302. This bullet is designed for the 7.35 Italian and it uses standard 7mm gas checks.

.30 & .31 CALIBER (.308 to .313 Dia.)

112 GRAINS

Bullet #311316 — A gas check bullet having two grooves and a normal cast diameter of .313. While this bullet was designed primarily for the 32/20 cartride, it will also work well in small capacity cases such as 30 M1 Carbine. Largest suggested sizing diameter is .311.

115 GRAINS

Bullet #3118 — A plain base bullet with two grooves and a normal cast diameter of .312. This bullet was designed primarily for the 32/20 cartridge. Largest suggested sizing diameter is .311.

115 GRAINS

Bullet #311359 — A gas check bullet having two grooves and a normal cast diameter of .312. This bullet was designed for use in small capacity cases. Largest suggested sizing diameter is .311.

131 GRAINS

Bullet #311410 — A plain base, two groove bullet which has a normal cast diameter of .313. This bullet is the best choice for the 30 M1 Carbine. Largest suggested sizing diameter is .311.

152 GRAINS

Bullet #311466 — A gas check, six groove bullet of Loverin design which has a normal cast diameter of .312. A very accurate 30 caliber bullet. Largest suggested sizing diameter is .311.

170 GRAINS

Bullet #311291 — A gas check, three groove bullet which has a normal cast diameter of .312. This is our most popular 30 caliber bullet. It is best suited for rifles which use a .308 sizing diameter. Largest suggested sizing diameter is .311.

173 GRAINS

Bullet #31141 — A gas check, three groove bullet which is very similar to #311291, but with a flat nose. It has a normal cast diameter of .311. Largest suggested sizing diameter is .309.

180 GRAINS

Bullet #311332 — A gas check, two groove bullet which has a normal cast diameter of .313. This bullet is very popular for 30/06 and .300 H & H cartridges. Largest suggested sizing diameter is .311.

180 GRAINS

Bullet #311407 — A gas check bullet of Loverin design, it has eight grooves and a normal cast diameter of .314. This bullet is very accurate in those 30 calibers which can handle a bullet of this weight. Largest suggested sized diameter is .312.

190 GRAINS

Bullet #311334 — A gas check bullet having two grooves and a normal cast diameter of .310. While the bullet was designed for the 30/40 Krag cartridge it works well in most other 30 caliber which can handle this bullet weight. Largest suggested sized diameter is .308.

202 GRAINS

Bullet #311299 — A gas check bullet having two grooves and a normal cast diameter of .314. An excellent bullet for the .303 British cartridge. Largest suggested sized diameter is .313.

210 GRAINS

Bullet #311290 — A gas check bullet having two grooves and a normal cast diameter of .311. This is an excellent heavy bullet for those 30 calibers which will handle this bullet weight. Largest suggested sized diameter is .309.

214 GRAINS

Bullet #311284 — A gas check bullet having three grooves and a normal cast diameter of .315. A very accurate heavy bullet for those 30 calibers which will handle this bullet weight. Largest suggested sizing diameter is .313.

.32 CALIBER (.320 Dia.)

134 GRAINS

Bullet #321427 — A gas check bullet having two grooves and a normal cast diameter of .322.

151 GRAINS

Bullet #321298 — A plain base bullet having three grooves and a normal cast diameter of .322.

161 GRAINS

Bullet #321317 — A gas check bullet having two grooves and a normal cast diameter of .323.

181 GRAINS

Bullet #321297 — A gas check bullet having three grooves and a normal cast diameter of .324. This bullet was originally designed for the 32 Winchester Special Cartridge.

8mm (.321 to .323 Dia.)

103 GRAINS

Bullet #32360 — A plain base bullet having two grooves and a normal cast diameter of .323.

115 GRAINS

Bullet #32359 — A plain base bullet having three grooves and a normal cast diameter of .324. This bullet is for use in 8mm cartridges, but it is also popular in 32/40 cartridges when the rifle has an oversized groove diameter.

165 GRAINS

Bullet #323470 — A gas check bullet of Loverin design having six grooves and a normal cast diameter of .321. A very accurate bullet.

243 GRAINS

Bullet #323378 — A gas check bullet having two grooves and a normal cast diameter of .323.

.338 CALIBER (.338 Dia.)

201 GRAINS

Bullet #338320 — A gas check bullet having two grooves and a normal cast diameter of .342.

247 GRAINS

Bullet #33889 — A gas check bullet having two grooves and a normal cast diameter of .341.

.348 CALIBER (.348 Dia.)

183 GRAINS

Bullet #350447 — A gas check bullet having two grooves and a normal cast diameter of .351. This bullet is our most popular bullet for the .348 Win. cartridge.

251 GRAINS

Bullet #350482 — A gas check bullet having three grooves and a normal cast diameter of .349.

.351 CALIBER (.352 Dia.)

167 GRAINS

Bullet #350319 — A gas check bullet having two grooves and a normal cast diameter of .352. This bullet was designed for the .351 Win. S.L. and uses .348 gas checks.

.35 CALIBER (.358 Dia.)

150 GRAINS

Bullet #358430 — A plain base bullet having two grooves and a normal cast diameter of .359. The bullet may be used in 35 caliber rifles or 38 Spec. and .357 handguns. A heavier version (195 grs.) is also available for rifles and handguns.

158 GRAINS

Bullet #358311 — A plain base, two groove bullet which has a normal cast diameter of .361. While this bullet was designed for the 38 special handgun cartridge, it works well in the 35 Remington rifle cartridge.

195 GRAINS

Bullet #358430 — A plain base bullet having three grooves and a normal cast diameter of .359. A lighter (150 gr.) version is also available.

204 GRAINS

Bullet #358315 — A gas check bullet having two grooves and a normal cast diameter of .360. This bullet was designed for 35 Remington and is very accurate.

232 GRAINS

Bullet #35897 — A gas check bullet having two grooves and a normal cast diameter of .359.

245 GRAINS

Bullet #358318 — A gas check bullet having two grooves and a normal cast diameter of .360. An excellent bullet for the .358 Winchester cartridge.

282 GRAINS

Bullet #3589 — A gas check bullet having three grooves and a normal cast diameter of .360.

.375 and .38 CALIBER (.375 Dia.)

249 GRAINS

Bullet #375248 — A plain base four groove bullet which has a normal cast diameter of .381.

264 GRAINS

Bullet #375449 — A gas check bullet having four grooves and a normal cast diameter of .377. This bullet is an excellent choice for the .375 H & H cartridge.

265 GRAINS

Bullet #375296 — A gas check bullet having four grooves and a normal cast diameter of .382. This bullet was originally designed for the 38/55 cartridge, but it works well in other 38 caliber rifles.

267 GRAINS

Bullet #375167 — A plain base bullet having three grooves and a normal cast diameter of .380. This bullet was originally designed for the 38/72 cartridge, but it is an excellent bullet for other 38 caliber cartridges.

38/40 CALIBER (.400 Dia.)

170 GRAINS

Bullet #40188 — A plain base bullet having two grooves and a normal cast diameter of .403. This bullet was designed for use in the 38/40 cartridge.

172 GRAINS

Bullet #40143 — A plain base bullet having two grooves and a round cast diameter of .403. This is our standard 38/40 bullet.

196 GRAINS

Bullet #40152 — A plain base bullet having two grooves and a normal cast diameter of .405.

.40 CALIBER (.400 to .408 Dia.)

212 GRAINS

Bullet #41028 — A plain base bullet having two grooves and a normal cast diameter of .411. An excellent bullet for the .401 Self Loader and may also be used in 41 Magnum Pistols.

240 GRAINS

Bullet #410426 — A plain base bullet having two grooves and a normal cast diameter of .411. An excellent bullet for the .401 Self Loader and may also be used in 41 Magnum Pistols.

288 GRAINS

Bullet #412263 — A plain base bullet having three grooves and a normal cast diameter of .413. This bullet was originally designed for the .405 Winchester cartridge.

.44 CALIBER (.424 to .431 Dia.)

205 GRAINS

Bullet #42798 — A plain base bullet having two grooves and a normal cast diameter of .432. This is our standard 44/40 bullet.

210 GRAINS

Bullet #429215 — A gas check bullet having two grooves and a normal cast diameter of .431. This is an excellent bullet for the .444 Marlin and may also be used in 44 Magnum Pistols.

232 GRAINS

Bullet #429360 — A plain base bullet having two grooves and a normal cast diameter of .430. Originally designed for the 44 Special cartridge this bullet is excellent for all 44 calibers.

245 GRAINS

Bullet #429244 — A gas check bullet of Thompson design having two grooves and a normal cast diameter of .434.

.45 CALIBER (.450 to .454 Dia.)

378 GRAINS

Bullet #457483 — A gas check bullet having three grooves and a normal cast diameter of .458. Originally designed for the 45/70 cartridge this bullet may also be used in the .458 Winchester.

385 GRAINS

Bullet #457124 — A plain base bullet having four grooves and a normal cast diameter of .460. This is our standard bullet for the 45/70, but it is also a good bullet for other 45 caliber rifles.

475 GRAINS

Bullet #457406 — A gas check bullet having four grooves and a normal cast diameter of .460. An excellent bullet for 45 caliber rifle cartridges.

545 GRAINS

Bullet #462560 — A gas check bullet having two grooves and a normal cast diameter of .463. A very good bullet for 45 caliber Magnum cases.

ALL BULLETS ARE PICTURED ACTUAL SIZE

JACKETED PISTOL BULLETS

.22 CALIBER (.222 Dia.)

40 GRAINS

Pictured is a Remington soft point. This bullet is designed primarily for the 22 Remington Jet cartridge.

Note — Bullets of .224 dia. for use in the 221 Fireball cartridge may be found under the Jacketed Rifle Bullet Listing.

.30 CALIBER (.222 Dia.)

85 GRAINS

The bullet pictured is a Remington full metal case. This bullet is designed for use in the .30 Mauser cartridge, but is also workable in the .30 Luger.

93 GRAINS

The bullet pictured is a Remington full metal case. Similar bullets of the same weight are available from Winchester and Norma. These bullets are designed for use in the .30 Luger cartridge.

71 GRAINS

The bullet pictured is a Remington full metal case. A similar bullet is also available from Winchester. Both bullets are designed for use in the .32 A.C.P. cartridges.

9mm (.354 Dia.)

124 GRAINS

The bullet pictured is a Remington full metal case which is designed for use in 9mm Luger cartridge.

.38 CALIBER (.355 Dia.)

95 GRAINS

The bullet pictured is a Remington full metal case. A similar bullet is also available from Winchester. While both bullets are designed for use in the .380 Auto cartridge they are also workable in the 9mm Luger.

130 GRAINS

The bullet pictured is a Remington full metal case, but a similar bullet is also available from Winchester. Both bullets are designed for use in the .38 A.C.P. and .38 Super Auto cartridge.

.38 CALIBER (.357 Dia.)

146 GRAINS

The bullet pictured is a Speer half jacket, hollow point which is designed for use in the .38 Special and the .357 Mag. cartridge. These bullets should not be used for loads which are lighter than those listed for they tend to shed their jackets in the barrel, when used at low velocity.

158 GRAINS

The bullet pictured is a Remington soft point. This is an excellent jacketed bullet for the .38 Special and the .357 Magnum cartridge.

160 GRAINS

The bullet pictured is a Speer half jacket which is designed for use in the .38 Special and .357 Magnum cartridge. These bullets should not be used with light loads or at low velocities as they tend to shed their jackets in the barrel when used at lower speeds.

.41 CALIBER(.410 Dia.)

210 GRAINS

The bullet pictured is a Remington soft point which is designed for use in the .41 Magnum cartridge.

.44 CALIBER (.429 to .431 Dia.)

(see Jacketed Rifle Bullet listing)

.45 CALIBER (.450 to .451 Dia.)

185 GRAINS

The bullet pictured is a Remington full metal case, Wad Cutter. A similar bullet is also available from Winchester. Both bullets are designed for use in the .45 A.C.P. cartridge.

230 GRAINS

The bullet pictured is a Remington full metal case. A similar bullet is also available from Winchester. They are designed for use in the .45 A.C.P. cartridge.

.45 CALIBER (.454 Dia.)

250 GRAINS

The bullet pictured is a Hornady half jacket which is designed for use in the .45 Colt cartridge. These bullets should not be used at low velocity as they tend to shed their jackets in the barrel when used at low speeds.

ALL BULLETS ARE PICTURED ACTUAL SIZE

CAST LEAD ALLOY PISTOL BULLETS

.22 CALIBER (.222 to .224 Dia.)

37 GRAINS

Bullet #225107 — This gas check bullet has one groove and a normal cast diameter of .226.

44 GRAINS

Bullet #225438 — This gas check bullet has three grooves and a normal cast diameter of .227. It is an excellent bullet for the .221 Rem. Fireball.

49 GRAINS

Bullet #225415 — This is a very accurate .22 caliber bullet which has two grooves and uses a gas check. It has a normal cast diameter of .228.

.30 & .32 CALIBER (.308 to .314 Dia.)

77 GRAINS

Bullet #311252 — This is a good bullet for the .32 A.C.P. cartridge. It has a plain base, two grooves, and a normal cast diameter of .313.

84 GRAINS

Bullet #313249 — This round nose bullet has a plain base and two grooves. It's normal cast diameter is .313.

84 GRAINS

Bullet #311227 — This round nose bullet has a plain base and two grooves. It's normal cast diameter is .313.

88 GRAINS

Bullet #311419 — This bullet uses a gas check, has one groove and a normal cast diameter of .314.

93 GRAINS

Bullet #313226 — This is a plain base bullet having two grooves and a normal cast diameter of .314.

9mm, .357 & .38 CALIBER (.354 to .360 Dia.)

75 GRAINS

Bullet #358101 — This bullet has a plain base and wad cutter design. It has two grooves and a normal cast diameter of .359. It is an excellent short range practice bullet for .38 and .357 revolvers.

92 GRAINS

Bullet #358242 — A round nose bullet with one groove and a normal cast diameter of .363. This is an excellent bullet for the .380 auto cartridge. (also available in 121 gr. weight).

112 GRAINS

Bullet #358425 — This is a wad cutter bullet having a plain base, 2 grooves and a normal cast diameter of .361. Due to its nose design it should not be seated flush with the case mouth.

121 GRAINS

Bullet #358242 — This round nose bullet has a plain base, two grooves and a normal cast diameter of .359. It is a good bullet for the 9mm Luger cartridge. (Also available in 92 gr. weight.)

121 GRAINS

Bullet #356402 — This bullet is our most popular choice for the 9mm Luger cartridge. It has a plain base, one groove and a normal cast diameter of .359.

133 GRAINS

Bullet #358480 — This semi-wad cutter bullet has a plain base, two grooves and a normal cast diameter of .361.

141 GRAINS

Bullet #358495 — This is a plain base bullet of wad cutter design. It has four grooves and a normal cast diameter of .360. The popularity of this particular bullet attests to its superb accuracy.

150 GRAINS

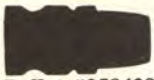
Bullet #358430 — This round nose bullet has two grooves and a normal cast diameter of .359. While it is basically a .38 caliber pistol bullet, it is sometimes used in the .35 Remington rifle cartridge.

155 GRAINS

Bullet #358156 — This is a gas check bullet of Ray Thompson's design. It has three grooves and a normal cast diameter of .360.

158 GRAINS

Bullet #358311 — This is our most popular 158 gr. .38 special bullet. It has a plain base, two grooves and a normal cast diameter of .360. The bullet may also be used in the 9mm Luger cartrridge.



168 GRAINS

Bullet #358429 — This is a plain base bullet of Elmer Keith design. It has two grooves, a normal cast diameter of .361 and is very accurate.

195 GRAINS

Bullet #358430 — This round nose bullet has a plain base, three grooves and a normal cast diameter of .359. It is also available in 150 gr. weight.

.38/40 CALIBER (.400 Dia.)

170 GRAINS

Bullet #40188 — This bullet was designed especially for the .38/40 cartridge. It has a plain base, two grooves and a normal cast diameter of .403.

172 GRAINS

Bullet #40143 — This is our most popular .38/40 bullet. It has a plain base, two grooves and a normal cast diameter of .403.

.41 CALIBER (.410 Dia.)

199 GRAINS

Bullet #41026 — This wad cutter bullet has a plain base, three grooves and a normal cast diameter of .414. It is very accurate.

212 GRAINS

Bullet #41032 — This bullet is a semi-wad cutter with a plain base and two grooves. It has a normal cast diameter of .411 and is an excellent choice for the .41 S & W Magnum.

212 GRAINS

Bullet #41028 — This round nose bullet has a plain base, two grooves and a normal cast diameter of .414.

215 GRAINS

Bullet #410610 — This is an excellent bullet for the .41 S & W Magnum. It is a gas check design having two grooves and a normal cast diameter of .412.

217 GRAINS

Bullet #41027 — This is a hollow base, wad cutter having five grooves and a normal cast diameter of .413.

240 GRAINS

Bullet #410426 — This round nose bullet has a plain base and two grooves. It has a normal cast diameter of .411 and is excellent for the .401 Win. or .41 S & W Magnum.

.44 CALIBER (.424 to .431 Dia.)

180 GRAINS

Bullet #429348 — This plain base, wad cutter has two grooves and a normal cast diameter of .432.

200 GRAINS

Bullet #429303 — This is a gas check bullet having two grooves and a normal cast diameter of .432.

205 GRAINS

Bullet #42798 — This is a plain base bullet having two grooves and a normal cast diameter of .432.

210 GRAINS

Bullet #429215 — This gas check bullet has two grooves and a normal cast diameter of .431. It is a very accurate bullet in most .44 caliber guns.

232 GRAINS

Bullet #429360 — This is a semi-wad cutter bullet having two grooves and a normal cast diameter of .430.

245 GRAINS

Bullet #429383 — This round nose bullet has a plain base, two grooves and a normal cast diameter of .432.

245 GRAINS

Bullet #429421 — This is a very accurate bullet of Elmer Keith's design. It has a plain base, two grooves and a normal cast diameter of .431.

245 GRAINS

Bullet #429244 — This is a gas check bullet having two grooves and a normal cast diameter of .434.

.45 CALIBER (.450 to .454 Dia.)

175 GRAINS

Bullet #45468 — This is a hollow base bullet having two grooves and a normal cast diameter of .456. It is a good, lightweight bullet for the .45 Colt cartridge.

185 GRAINS

Bullet #452389 — This is a plain base, wad cutter having two grooves and a normal cast diameter of .457.

200 GRAINS

Bullet #452460 — This is a semi-wad cutter having two grooves and a normal cast diameter of .454.

225 GRAINS

Bullet #452374 — This is our standard bullet for the .45 A.C.P. cartridge. It has a plain base, one groove and a normal cast diameter of .455.

235 GRAINS

Bullet #454309 — This is a plain base, wad cutter having three grooves and a normal cast diameter of .456.

238 GRAINS

Bullet #452423 — This is a very accurate bullet of Keith design. It has a plain base, two grooves and a normal cast diameter of .454.

250 GRAINS

Bullet #454190 — This is our standard bullet for the .45 Colt cartridge. It has a plain base, two grooves and a normal cast diameter of .457.

255 GRAINS

Bullet #454424 — This is a plain base bullet of Elmer Keith design. It is a very accurate bullet for the .45 Colt cartridge, has two grooves and a normal cast diameter of .457.

ACCURACY WITH JACKETED BULLETS

Before getting into the subject of accuracy in this chapter, it is necessary to qualify our terms. "Accuracy" means different things to different shooters. Its interpretation depends to a large extent upon the kind of shooting the individual is accustomed to — the type of rifle and cartridge he uses — and of course, the human factor — his ability as a marksman.

Whether it is loaded with factory ammo, or reloads, the trusty old deer rifle remains pretty much of a hunting weapon rather than a target gun. Lever action or pump action rifles may be perfectly adequate for hunting, but they will never shoot in the same accuracy class as bolt action target rifles. Nor will a reloaded 30/30 cartridge ever achieve the superior ballistics of, say, a .270 Winchester. Therefore, we are considering accuracy herein only as it pertains to improving the results of a given rifle or cartridge. No matter how accurate your rifle may be with a factory loaded round, it can be made more accurate by employing the reloading procedures as set forth in this accuracy chapter.

First, make a careful appraisal of your firearm. Sure, it may not have been intended for bench rest shooting, but, if it is maintained in the proper condition, it is capable of optimum accuracy only restricted by its design and caliber. A reasonably smooth trigger pull is a must. Sighting equipment should be of good quality and in top condition. Also, it may be wise to have a competent gunsmith check the headspace, screws, bedding, crowning, throat and bore. A little help from an expert can save you plenty of time, trouble and ammunition.

We suggest that you carefully slug your barrel to determine its exact groove diameter (See "Accuracy With Cast Bullets" chapter). If your groove is not of a standard size for which you are able to purchase the correct diameter jacketed bullets, then the accuracy potential of your rifle is limited before you start. If your groove diameter is on the tight side, it could produce dangerous pressures with the standard size jacketed bullet. For both safety and accuracy in non-standard groove rifles, we suggest the use of cast lead alloy bullets.

LOADING FOR ACCURACY WITH A JACKETED BULLET

It may be argued by some that, in this chapter, we should include such procedures as gauging flash holes for uniformity, measuring case volume and rotating bullets to insure their balance. However, we are covering only the loading procedures which our tests have shown have a definite bearing on the general accuracy of a load. In reloading, you may discover certain individual characteristics of your rifle which suggest to you slight variations in loading methods that seem to improve your accuracy. If so, by all means adopt them.

If you have established the safety of the load (as explained in the Pressure chapter), you do not need new cases for accuracy. The cases you do use, however, must be in good

condition, uniform in every way, of the same brand, and fired an equal number of times. Trimming is vitally important, and all cases must be trimmed to the exact same length.

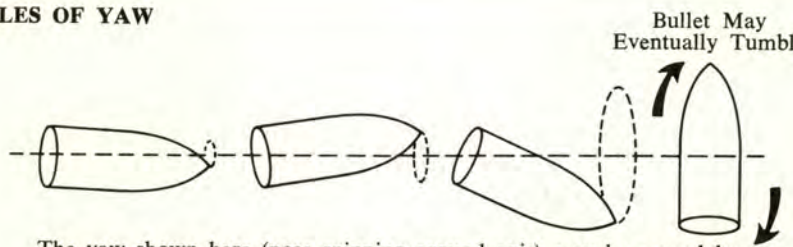
Contrary to the usually accepted procedure, we do not recommend that cases be neck resized only. Our tests indicate that neck-sizing in itself does not produce a noticeable increase in accuracy, while conventional full-length resizing does make a finished round that will chamber more freely. For consistency, it is recommended that you match your primer brand to your case brand — if possible.

The type of powder should be carefully selected. A good powder to start with is the one listed for the accuracy load in the Data section under your cartridge and bullet weight.

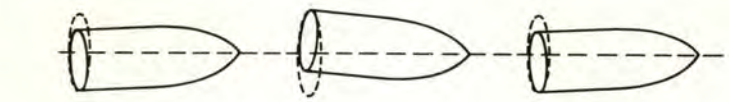
Weigh all of your charges carefully on a powder scale. If very slight variations in a particular powder charge seem to be critical to the accuracy of the load, try another powder. Chances are it will work better with your particular rifle and component combination.

As explained in the previous chapter on "Bullets", the weight, length and shape of the projectile are important to accuracy. The length of the bullet must be compatible to the rifling twist and velocity, or the bullet will become erratic in flight. When a bullet spins erratically, it is said to be yawing. The illustration following shows how and why a bullet yaws.

EXAMPLES OF YAW



The yaw shown here (nose spinning around axis) may be caused by a defect in the bullet, by imperfect crowning, or by a washed out bore.



The yaw shown here (base spinning around axis) may be caused by excessive velocity or the wrong combination of twist to bullet length. Bullets that yaw in this manner in early flight sometimes settle down and spin true as they lose velocity.

As bullets are never absolutely perfect in balance and weight, select only those which are the most uniform. Weigh the bullets carefully on a standard powder scale. Bullets that vary more than 1/2 grain (+ or —) from advertised weight should be rejected.

For the utmost in reloading accuracy, the use of three reloading dies is mandatory. A Three-Die Set differs from a Two-Die Set in that it contains a separate neck expanding

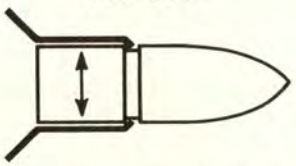
die. This die (Lyman "M" Die) is equipped with a 2-step expanding plug. The first step of the plug expands the neck of the cartridge to slightly under bullet diameter. The second step expands the first 1/16″ of the neck to slightly over bullet diameter, allowing the bullet to enter the case freely. The real advantage to this is that it insures precise "bullet pull" from shot to shot. Consistent bullet pull (tension of neck on seated bullet) is highly important to accuracy as each bullet must release with exactly the same amount of pressure if your shots are to remain consistent. The following illustration shows a standard Three-Die Rifle Set which features 2-step neck expanding.

LYMAN STANDARD THREE-DIE SET

- Full-Length Resizing and Decapping
- 2-Step Neck Expanding
- Bullet Seating and Crimping
- Die Adjusting Wrench

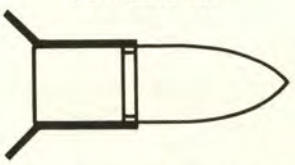
Careful seating of the bullet is also important for accuracy. With a Three-Die Set the bullet can be started into the case neck with your fingers. This is a great help as the bullet can now be aligned visually before it enters the seating die. Operate the press handle slowly and with care. Be certain that the seating die is locked tightly in adjustment. For accuracy loading, **do not use** the crimping feature of the die. Seat the bullets friction tight only. Crimping is actually harmful to consistent bullet pull for two reasons: 1. It is nearly impossible to crimp each case exactly the same each time. 2. The pressure used in crimping has a tendency to bulge the case neck away from the bullet. In most instances, crimping actually loosens the bullet in the neck and lightens bullet pull (see illustration).

CRIMPED



While Bullet Will Not Move Forward or Backward, It May Be Rocked Sideways.

UNCRIMPED



Most Uniform Bullet Pull Is Afforded When The Neck Walls Are Tight Against The Bullet.

To obtain perfection in seating a jacketed bullet when loading a bottle-neck rifle case, we suggest the use of a Lyman P-A* (precision alignment) bullet seating die. These dies are available for most all bottle-neck cartridges and they contain a sliding inner sleeve which holds the bullet and neck of the case in consistent alignment throughout the seating operation.

*NOTE. At the present time the P-A Die is not offered for sale in a Three-Die Set. We would advise those who are interested, to purchase the Lyman Two-Die Deluxe Rifle Set and make a separate purchase of a "M" neck expanding die. When used in combination, these three dies will produce the best possible results with bottle-neck cases and jacketed bullets.

EXCEEDING MAXIMUM OVERALL LENGTH

Throughout this Handbook we have tried to emphasize the importance of adhering to maximum chamber dimensions. We have stated that a bullet which is set too far forward (exceeding the maximum overall cartridge length) will boost pressures, and indeed it will. Understanding, however, and a cautious approach does allow us certain latitudes. There are times, in the interests of accuracy, when the Handloader can exceed the maximum overall length listed. With some rifles (particularly those chambered for the .257 Roberts) it is necessary to set the bullet well forward if we are to obtain our best accuracy. Some rifles have a long chamber throat and give their best results when the bullet is seated just short of touching the rifling.

The reader must realize that seating bullets in this manner does have its effect on chamber pressure. In order to do it safely, requires that the handloader establish his seating depth and then work up this charge slowly as explained in the "Pressure" chapter. Also, it should be realized that cartridges loaded in this manner will not normally function through the magazine of the rifle. They are usually too long. If the load is accurate, however, it does have an application for single shot, varmint and target work and for these purposes it is sometimes done.

To accomplish this, make up a dummy round (less powder and primer). Start a bullet a short distance into the case neck. Now, chamber this cartridge in your rifle. As you close the bolt the bullet will be seated into the case just far enough so that it touches the rifling. Of course, we can't leave the bullet in this position, but at least we know where the rifling is in relation to the bullet.

Remove the dummy round from the rifle and insert it into your bullet seating die. Adjust the seating stem of your die so that the bullet is seated about 1/32″ **deeper** in the case than it was when it came from the rifle chamber. Remember! you have just created a pressure condition which must be compensated for by working up the load slowly and carefully.

For further information on this subject, we recommend that you also read the "Accuracy With Cast Bullets" chapter which contains data that will be equally helpful in loading jacketed bullets.

ACCURACY WITH CAST BULLETS

You should study the two preceding chapters ("Bullets" and "Accuracy With Jacketed Bullets") before reading this chapter because much of the information therein, which is not repeated in this chapter, also pertains to cast bullet shooting.

As explained in the "Bullets" chapter, the cast bullet must be restricted to a more moderate velocity than its jacketed counterpart because the cast bullet is constructed of softer metal. Even bullets of #2 alloy are not considered as hard in comparison with the strength of some jacketed bullets. The shape or design of the cast bullet is to some extent indicative of its potential accuracy. Because the bullet is soft, it requires design features that will afford the most positive alignment in the throat and bore.

In developing loads for this Handbook, we fired some 20,000 cast bullets of various designs and calibers. With the exception of shotgun slugs and muzzle loading bullets, #2 alloy was used exclusively. All bullets were sized to groove diameter or as near to groove diameter as possible. Overall tests results were excellent and in most instances the cast bullets gave better accuracy than jacketed bullets when used in the same rifle or pistol. **Leading of the bore was never experienced** in all of our testing.

The best results of our extensive testing were used in determining the suggested loads and bullet designs which are listed in the Data Section of this Handbook. Generally, bullets with blunt or round noses were found to be the most accurate. While a great many pointed bullets shoot well, the bullet must be of a design that has a relatively short ogive. Such bullets have their greatest weight mass bearing directly on some portion of the rifling which gives the bullet maximum alignment in the throat and bore of the rifle.

The following illustration will further clarify our test results with various cast bullet design. Although some shooters may have experienced good results with a long ogive bullet in a particular rifle, our text is based on the results of testing **many** rifles with **many** bullet designs. We are stating the rule rather than the few exceptions.

These four shapes are basic to cast bullet design. Actual bullets may vary to some extent, but, generally, they fall into one of these four categories.

1 & 2. (IDEAL DESIGNS) Bullets that conformed to either of these general shapes performed very well in our testing. Due to their short ogive, the greatest weight mass bears on some portion of the rifling. The driving bands bear directly on the groove, while the nose acts as a pilot to align the bullet in the throat and bore.

3. (LOVERIN DESIGN) Bullets having this general shape performed extremely well in all of our testing. Due to their short ogive, the greatest weight mass bears directly on the groove. While the design does not always provide for a section of the bullet to bear on the lands, the many driving bands of groove diameter keep them well aligned.

4. Bullets of this general shape proved to be the worst performers in our testing. Their long flowing ogives leave a large portion of the bullet unsupported by the rifling. Cast bullets of this general shape can easily mis-align themselves as they enter the throat and bore.

While the foregoing illustration deals primarily with cast bullets designed for use in rifles, the same fundamentals apply to pistol bullets. Pistol bullets, however, are all basically wad cutters in their design, and you would be hard pressed to find a cast pistol bullet with other than a short ogive.

BLENDING ALLOYS INTO BULLET METAL

Throughout this Handbook, the exclusive use of #2 alloy is recommended for rifle and pistol loads. (Use pure lead for shotgun slugs and muzzle loading bullets). We consider this relatively hard bullet material essential for cast bullet accuracy. If they are designed correctly and driven at the proper velocity, bullets of #2 alloy are sufficiently tough so that they will not become deformed in the throat and bore. As these bullets do not expand readily, the purchase of hollow point moulds is suggested for making hunting bullets.

Several formulas for blending metals to make #2 alloy are listed in the "Bullets" chapter. Again, blending is important because, if it is not done properly, the bullet material will not be consistent and one bullet will contain more or less tin, etc., than another.

Besides the necessary alloy materials, a few inexpensive tools are also needed, such as: a lead pot, a lead dipper, a simple ingot mould. The kitchen stove (gas or electric), or a torch can be used to melt down the lead alloy. However, the heat source must be capable of heating the material to a temperature of about 800° and maintain it pretty constantly. A thermostatically controlled electric furnace (The Lyman Mould Master) is also available. An electric furnace, while it adds greatly to the ease and convenience of making bullets, is not essential.

Lyman Lead Pot

Lyman Ingot Mould

Lyman Lead Dipper

After the correct proportions of the various alloys are placed into the pot, or furnace, they are melted down, fluxed, stirred and poured into the ingot mould. This supplies you with small 1½″ x 3″ bars of bullet metal to use later in your casting. When melting and blending your bullet metal, follow the same procedure and use the same care as when preparing metal for the mould. If the same temperature requirements and fluxing, stirring, etc., are not adhered to, the blend of the metals and bullet material will be inconsistent. The most common mistake in bullet casting is improper blending of the metal. If the tin content is not up to par, the bullets will lead the bore.

LYMAN MOULD MASTER FURNACE

A thermostatically controlled electric furnace adds greatly to the speed, ease and convenience of making bullets.

PREPARING METAL FOR THE MOULD

MELTING AND FLUXING

Place several ingots of bullet metal into your pot, or furnace, and heat them to about 750°. A Lyman Electric Furnace, due to its adjustable thermostat, allows you the best control of the metal temperature. If you are using some other heat source, however, you can play it by ear. Heat the metal for about twenty or thirty minutes until it becomes liquified and flows freely. It is then ready for fluxing.

As the metal melts, a gray scum will rise to the surface contrasting sharply with the quick-silver brightness of the molten lead. DO NOT REMOVE THIS SCUM. This is tin, the most valuable component of the bullet metal. Tin, being lighter, will tend to float to the top of the mixture. Fluxing will recombine the tin-lead-antimony mixture. This operation is extremely important and it must be followed carefully!

To flux the metal, merely drop a small bit of tallow, beeswax, or bullet lubricant into the mixture. A smokey gas will rise from the top of the pot and this gas should be immediately ignited with a match. This will eliminate the smoke. Stir the mixture with the dipper, working the floating tin through the molten lead. As you stir, hold the dipper so the cup side is down and raise it out of the metal with each stirring stroke. This scoops air into the mixture and helps the flux.

Metal that has been properly fluxed will take back the tin, leaving the surface almost mirror bright and flecked with small particles of black and brown impurities. Skim off and discard these impurities. Always flux the metal, after adding to the pot, or whenever, by its appearance, it seems to need it. Remember, you cannot overdo this fluxing operation. While the dipper is not in use, it should be left in the molten metal to keep it hot.

CASTING BULLETS

After the metal has been fluxed, and is hot enough to pour easily through the dipper, it is ready for casting. In addition to the mould, you should have on hand a hardwood stick (about 10″ long) to be used for opening the mould. Also, pad a small area of your bench with an old piece of cloth material. This will soften the fall of the hot bullets as they drop from the mould, and prevent them from being damaged.

While there is no set way to cast good bullets, we do offer the following as a suggested method. Fill the dipper half full of metal and place the spout of the dipper against the pouring hole as shown in "A" of the following illustration. Holding the mould and dipper together, slowly turn them into a vertical position with the dipper on top of the mould as pictured in "B."

A

B

The extra metal that runs over the top of the mould is called sprue. When it hardens, which takes only several seconds, pick up the hardwood stick and tap the sprue cutter sharply. This will separate the sprue from the base of the bullet. Drop the sprue into a cardboard box, or other receptacle. Open the mould and let the bullet fall to the pad. If the bullet does not drop out readily, use the stick to rap the hinge rivot sharply, as shown in the illustration. Use only wood for this purpose and never strike the mould blocks themselves.

If Bullet Does Not Drop Readily, Strike The Hinge Rivot.

As the mould will be cool, your first bullets will be imperfect. Casting bullets, one after the other, will bring the mould to the proper temperature. If you wish, the mould can be preheated by placing it on the rim of your furnace, or along side your lead pot on the stove. Never, under any circumstances, dunk the mould in the molten metal!

Wrinkled bullets indicate that the mould, and/or metal, is too cool. Frosted bullets indicate that the mould, and/or metal, is too hot. Good bullets should be clean, sharp, and fill the mould. Imperfect bullets should be collected and, along with the sprue, returned to the pot.

1. GOOD BULLET — TEMPERATURE CORRECT
2. WRINKLED BULLET — TEMPERATURE TOO COOL
3. FROSTED BULLET — TEMPERATURE TOO HOT

Bullets selected for accuracy shooting should be carefully weighed on the reloading scale. This reveals air pockets that may have formed in the bullet, lightening or unbalancing it. The actual weight of your bullets will depend pretty much on the consistency of your alloy material, and it may vary slightly from lot to lot. Weigh about twenty or thirty bullets out of each group and determine an average bullet weight. Reject any bullets that vary more than ½ grain (+ or —) of this weight. Rejected bullets may be saved and recast at a future date.

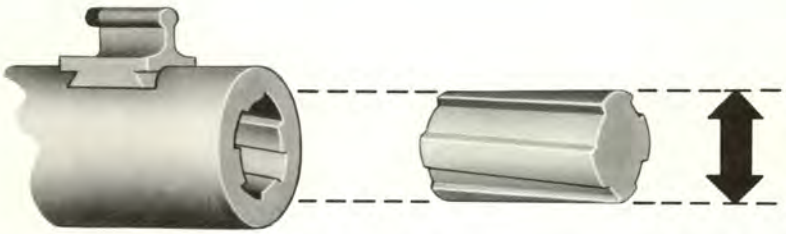
DETERMINING YOUR BULLET DIAMETER

SLUGGING YOUR BARREL

Before you can expect much in the way of accuracy from your rifle or handgun, you must make sure that the sized diameter of the cast bullet is correct for your particular firearm. Tolerance ranges being as broad as they are (particularly with older guns or those of foreign make), we suggest slugging the barrel to ascertain the exact bullet size.

Slugging the barrel is really quite simple, but it does require a little care and patience if it is to be done correctly. First, make up a soft lead slug which is slightly larger than the groove size of the firearm. This can be a lead bullet that you have expanded in a vise, or just a piece of soft lead whittled to size. The slug is carefully tapped into the muzzle of the firearm and then driven all the way through the barrel with a suitable rod (such as a cleaning rod). Do not use a thin cleaning rod as it will penetrate the slug and become lodged in the bore. Use a rod that is wide enough to drive the slug ahead of it. After the slug has been carefully tapped through the barrel, it will be perfectly engraved and clearly marked by both the lands and the groove.

With a micrometer, measure the slug across its widest diameter (see illustration). This is the groove diameter of your firearm and the proper sized diameter for your cast bullet. Your bullet sizing die should correspond as closely as possible to this dimension.

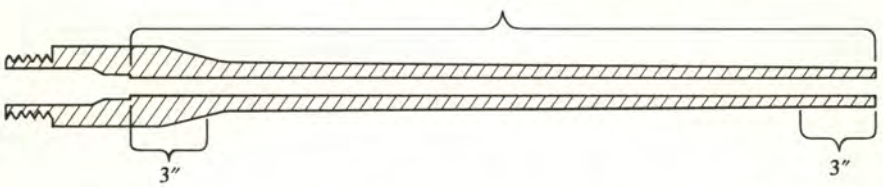


With a micrometer, measure the diameter of this slug at its WIDEST POINT. This is the groove diameter of your rifle.

If the barrel is in poor condition, or, if it has a worn throat or muzzle, chances are that it will not be very accurate with any size bullet. To shoot well, the barrel must have a consistent groove diameter from one end to the other. While there is little you can do to correct a poor barrel, at least you should be aware of your problems before you start.

To check for a worn (belled) muzzle, drive another slug about 3″ into the end of the barrel and return it by driving it back out. Do not drive this slug all the way through. Also check the throat by driving another slug (from breech) to about 3″ past the chamber and then return it. With a micrometer, measure the groove diameter of both of these slugs and compare their dimension to that of the slug which you drove through the barrel. If all three slugs agree, then your barrel has a consistent diameter throughout its length, and you may expect good results from cast bullets of this size.

Driving a soft lead slug through the barrel will determine its groove diameter. This is also the proper sized diameter for your cast bullet.



A soft slug driven about 3″ past the chamber and then returned, will check the throat diameter. If the diameter of this slug is larger than the one driven through the barrel, the throat is worn.

A soft slug driven about 3″ past the muzzle and then returned will check the muzzle diameter. If the diameter of this slug is larger than the one driven through the barrel, the muzzle is worn.

CHOOSING A BULLET SIZING DIE

After you have determined the exact bullet size, you will need a bullet sizing die (G, H & I) of this diameter, or as near to it as possible. Lyman bullet sizing dies have been newly designed to supply a swaging rather than a shearing action in reducing bullet diameter. The mouth of the "H" die contains a gentle taper which allows the gas check and bullet to start into the die easily. The exact tolerance and ultra-smoothness of the hardened inner chamber completely eliminates shearing of lead and produces a perfectly cylindrical bullet. As this swaging action compresses and work-hardens the alloy, it does not reduce the bullet weight, but leaves it tougher, smoother and more accurate.

IDEAL BULLET LUBRICANT
was used exclusively throughout our cast bullet testing.

"G" TOP PUNCH
Order by bullet number.

"H & I" SIZING ASSEMBLY
Order by groove diameter.

The Lyman #45 Lubricator and Sizer

When equipped with the proper G, H & I Dies, this tool supplies the leverage to size your bullets to the correct diameter. It will also force lubricant under pressure into the bullet grooves. Lyman Ideal Bullet lubricant is moulded specifically to fit the reservoir of this machine. For complete price information, see Lyman catalog.

MULTI OR SHALLOW-GROOVE RIFLING

Throughout our testing of cast bullets, we had difficulty with one type of rifling that proved to be somewhat incompatible to cast bullet shooting. This was the "Multi", or what is commonly known as "Shallow-Groove" rifling. While jacketed bullets performed exceptionally well when fired from these rifles, cast bullets had a tendency to keyhole when fired from the same barrels. To prevent the cast bullets from stripping and to eliminate the keyholing, we were forced to reduce their velocity to under 1600 F.P.S. in shallow groove barrels.

You will find that the maximum velocity loads shown in the cast bullet Data are in most cases workable only with firearms having standard type rifling. If your rifle has a shallow-groove barrel, we recommend that you stay with the suggested starting loads for best results. Some military rifles of .303 British caliber which have extremely shallow grooves are also encountered. While these rifles are not multi-grooved, their shallow grooved barrels will necessitate the same reduction in cast bullet velocity.

USING THE PROPER DIES

When loading cast bullets for either rifle or pistol, the use of a Three-Die Set is mandatory. A Three-Die Set differs from a Two-Die Set in that it contains a separate neck expanding die. This die (Lyman "M" Die) is equipped with a 2-step expanding plug. The first step of the plug expands the neck of the cartridge case to slightly under bullet diameter. The second step expands the first 1/16″ of the neck to slightly over bullet diameter, allowing the cast bullet to enter the case freely without shaving lead and ensuring consistent bullet pull.

In the previous chapter ("Accuracy With Jacketed Bullets"), we cover the need for consistent bullet pull and the benefit of not crimping the bullet into the case. The same applies to cast bullets and perhaps even more so. Each bullet must release with exactly the same amount of pressure if your shots are to remain consistent. If you can get away without crimping, by all means do so. Of course, you have no choice with some cartridges for their heavy recoil, or the magazine style of the firearm, requires that a crimp be used.

LYMAN STANDARD THREE-DIE SET

- Full-Length Resizing and Decapping
- 2-Step Neck Expanding
- Bullet Seating and Crimping
- Die Adjusting Wrench

UNDERSTANDING VELOCITIES

It is sometimes mistakenly assumed that the velocities of reloaded ammunition do not compare favorably with the ballistics of factory ammunition. Factory advertised velocities tend to support this assumption. However, you must bear in mind that barrel lengths do affect ballistics. In many cases the factory figures were obtained in much longer barrels, than those in common use.

The following listing shows the actual chronographed velocities obtained with factory loaded ammunition in our test firearms. Variations can occur in different barrels of the same length. Slight variations also occur with different lots of ammunition from a given manufacturer.

Velocities shown were obtained at fifteen feet from the muzzle.

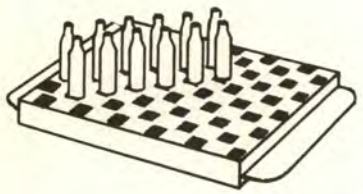
RELOADING ACCESSORIES

Every hobbyist, whether he is an amateur radio operator, photography bug, or reloader, likes to accumulate an impressive array of tools. In most cases extra equipment adds up to a faster or better job. In all cases it certainly makes sense to eliminate the little inconveniences which fall into the category of work. If some tricky little tool takes the work out of a job, but leaves all the fun, then why not buy it?

Reloading offers the hobbyist a good many accessory items which can be added to the basic tools pictured earlier in this Handbook. Some of these tools such as a case length gauge and case trimmer will be necessary if you are to continue reloading to any advanced degree. To make the reader aware of these items and to explain their function, we offer the following text and illustrations.

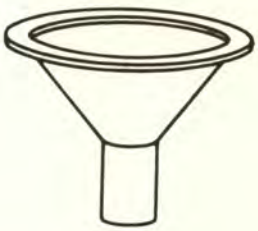


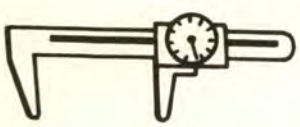
LOADING BLOCKS

These blocks are made of either plastic or wood and they are used to support empty, primed cases while charging them with powder. The use of these blocks not only speeds up reloading and prevents spillage of powder, but inasmuch as they provide a better order to your reloading bench, they help to eliminate the possibility of double charging a case.

POWDER FUNNEL

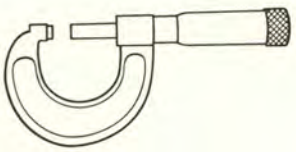
Every reloader should use a powder funnel. This inexpensive tool insures that all of the powder in the charge enters the case. Spilled granuals of powder not only detracts from the accuracy of our loading, but they eventually present a fire hazard if left laying around our bench.





CASE LENGTH GAUGE

Some accurate method of measuring or gauging case length is eventually required by every reloader. A vernier caliper, 4″ long or longer is an extremely efficient tool for measuring cases. A good vernier may be purchased at most any hardware store or you can use one of the case length gauges made for this purpose. Whatever you use, however, must be accurate.

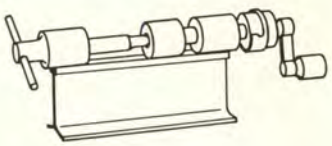


MICROMETER

A one inch micrometer is certainly a handy tool for measuring bullet diameter, head expansion, etc. It will not replace a good vernier however. A good vernier can be purchased for the price of a poor micrometer and it has a wider range of uses.

CASE TRIMMER

This item is used to trim cases back to a length which is compatible with the gun chamber (see case chapter). Some type of case trimmer will eventually be needed by every reloader. Many tools are available and we suggest that you visit your local reloading tool dealer and ask to see his selection.

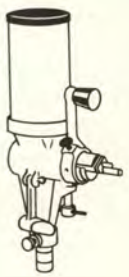


AUTO PRIMER FEED

Here is an attachment that most reloaders will eventually obtain. Its function is to feed primers automatically into your reloading press. This eliminates the separate handling of each primer and speeds up the reloading operation tremendously

POWDER MEASURE

Perhaps a better name for a powder measure is powder dispenser for it dispenses rather than measures powder. When used in conjunction with a powder scale, this is an excellent item. The measure is set, checked with the scale to insure its accuracy, and then used to meter out charges one after another. About every tenth round the measure should be rechecked with the powder scale.



PRIMER FLIPPER

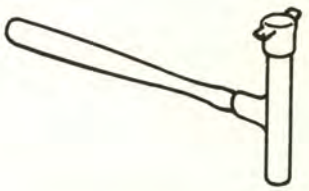
This is an amazing little tool which can save a lot of time in handling primers. It flips over primers so that they all lay in one direction (either base up or down). The tool is particularly handy when loading primers into a primer feed tube.

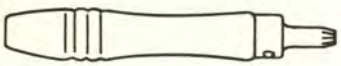
POWDER TRICKLER

This is an excellent item which is used in conjunction with a powder scale and sometimes a powder measure. The purpose of the Trickler is to control the flow of small amounts of powder into the scale pan. With a Trickler, you can add a few granuals of powder at a time and carefully bring the scale into balance. Sometimes a powder measure is set up to throw an under-weight charge. The charge is then dumped into the scale pan and brought into exact balance by adding powder from the Trickler.

BULLET PULLERS

There are several types of bullet pullers on the market. One of these tools is handy for the reloader who sometimes finds it necessary to remove bullets from live cartridges. The bullet puller allows you to salvage components without damage.



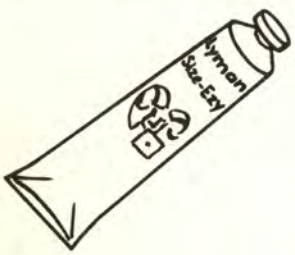


PRIMER POCKET REAMER

All reloaders who intend to use government cartridge cases should purchase one of these tools. The tool is used to clean out and remove the crimp from primer pockets on cases which originally had crimped-in primers.

SHELL CHAMFERING REAMER

The chamfering reamer is used to cut a slight taper on the case mouth. This allows for easier and smoother bullet seating. Cases are chamfered only once (after the first firing). They need not be chamfered at each reloading.



SIZE-EZY LUBRICANT

A suitable case lubricant is necessary to prevent cases from sticking in the resizing die. Lyman "Size-Ezy" was formulated specifically for this purpose. Remember, a little lubricant goes a long way, so use it sparingly. Also, wipe cartridges free of lubricant before firing.

GLOSSARY OF TERMS

Anneal: The process of altering the structure of any metal so as to relieve its working stresses and increase its ductility. See "Case" chapter in reference section for brass annealing.

Anvil: A metallic part of the primer. The blow from the firing pin crushes the priming mixture against the anvil causing ignition. See "Primer" chapter in reference section.

Ball: In military nomenclature this term refers to the bullet.

Ball Powder: This is a trade name for a double base smokeless powder developed by Olin Industries. It has a spherical or flattened spherical shape.

Ballistics: The science of projectiles in motion.

Ballistic Coefficient: Ratio of the sectional density of a bullet to its coefficient of form. Represents the projectiles ability to overcome the resistence of the air in flight .

Battery Cup: A type of primer used in shotshells which makes use of an outside cup to support it in the case. See "Primer" chapter in reference section.

Bearing Surface: That portion of the bullet surface which bears on or touches the bore.

Bell: To open the mouth of a case slightly in order to seat a bullet more easily. Also used in reference to a rifle barrel which is worn at the muzzle (belled muzzle).

Belted: A band which is formed into the head of some cases (magnum type) to strengthen the case and headspace the cartridge. See "Case" chapter in reference section.

Berdan: A common European priming system which makes use of an anvil formed in the case itself. See "Primer" chapter in reference section.

Boattail: A bullet design having a tapered base.

Bore: The inside diameter of a barrel before the rifling is cut.

Boxer: A common American primer named after Colonel Boxer. See "Primer" chapter in reference section.

Bullet: That portion of the cartridge which becomes a projectile when in flight. See "Bullet" chapter in reference section.

Burning Rate: A term which is used to describe the rapidity with which a given powder will burn. The term itself is a relative one based on a comparison with other powders. See "Powder" chapter in reference section.

Caliber: The approximate diameter of a bullet, or bore, expressed in decimals of an inch in English. In Europe where the metric system is used, this measurement is expressed in millimeters.

Cannelure: A groove (or grooves) cut around the circumference of a bullet. These grooves are normally used to hold bullet lubricant or to provide room or friction for crimping.

Case: The metal, plastic or paper container which holds all of the components of a round of ammunition.

Cast Bullet: Bullets for rifle or pistol which are cast from lead alloy. See "Bullet" chapter in reference section.

Center Fire: Refers to a cartridge having a centrally located primer in its base.

Chamber: That part of the bore at the breech which is formed to accept and support the cartridge.

Chamfer: To ream a taper on the inside of a case mouth.

Charge: The amount of powder used in the case at each loading. Also refers to the amount of shot used in a shotshell.

Choke: A constriction at the muzzle of a shotgun barrel designed to control the spreading of shot.

Chronograph: An instrument used to measure the velocity of a bullet.

Compressed Charge: A charge of powder which so nearly fills the case that it is compressed when the bullet is seated.

Components: Any of the various parts which go into the making of a cartridge.

Corrosion: The eating away of the bore by rust or chemical action.

Crimp: The bending inward of the case mouth to grip the bullet. With shotshells the term applies to the closure at the case mouth.

Crimped Primer: A forcing inward of the brass around the top of the primer pocket. This is frequently found on military cartridges and it is done to prevent set-back of primers. The crimp must be removed before repriming the case.

Drams Equivalent: Term used to indicate the approximate velocity of a shot charge by a comparison. See "Shotshell Ballistics and Tips" following Shotshell Data.

Drift: Deviation of a projectile from the line of departure due to its rotational spin or the force of wind.

Drop: The distance a projectile falls, calculated from the line of departure.

Double Base Powder: Smokeless powder made with nitroglycerine and nitrocellulose base.

Duplex Load: The use of two different powders in loading the same cartridge. It is not recommended and can be dangerous.

Energy: A projectiles capacity for doing work at a given range, expressed in foot-pounds.

Erosion: The wearing away of the bore due to friction.

Fireform: Reforming or changing the shape of a cartridge case by firing it in a chamber of the desired shape.

Flash Hole: A hole leading from the primer pocket to the inside of the case. See "Case" chapter in reference section.

Foot-Pound: A unit of kinetic energy equal to the effort required to raise a one pound weight, to a height of one foot, against the normal pull of gravity.

Freebore: The distance in the barrel, if any, which the bullet travels before it contacts the rifling. Some barrels are purposely relieved to allow the bullet considerable free movement before it strikes bore rifling.

Gas Check: A gilding metal cup which is used to protect the base of a cast lead alloy bullet from the burning effects of powder gase.

Gilding Metal: A copper-zinc alloy used for bullet jackets and gas checks.

Grain: A unit of weight measure. 437.5 grains equal one ounce.

Grooves: Spiral cuts in the bore of a firearm which cause the bullet to spin as it moves through the barrel.

Hangfire: Delayed ignition.

Headspace: The distance from the bolt face to that part of the chamber which acts as a stop and prevents the cartridge from moving forward. Also applies to the cartridge case. See "Pressure" and "Case" chapters in reference section.

Heel: The outer edge of the bullet base.

Hollow Point: A bullet design which features an axial hole at the point. The purpose of the hole is to aid expansion on impact.

Ignition: The action of setting the powder charge on fire.

IMR: Abbreviation for "Improved Military Rifle".

Jacket: The covering or skin of a bullet.

Keyhole: The imprint of a bullet which struck sidewise on target, rather than point first.

Lands: The raised portion of the rifling.

Line of Sight: An imaginary straight line from the eye, through the sights, to the point of aim.

Loading Density: Ratio of the volume of the powder charge to the volume of the case.

Mercuric Primer: A primer in which the priming mixture contains mercury.

Metal Case: A type of bullet which except for a small opening at the base, is completely encased in a jacket.

Mid-Range Trajectory: Refers to the distance the bullet raises above the line of sight. Mid range trajectory is calculated halfway between the muzzle and the target.

Minute-of-Angle: A unit of angular deviation equal to 1/60th of a degree. For practical purposes it is usually approximated as equal to one inch at 100 yards.

Misfire: The failure of a cartridge to fire after the primer is struck.

Muzzle: The front end of a barrel.

Muzzle Energy: See "Energy"

Muzzle Velocity: See "Velocity"

Neck: The forward portion of a cartridge case which grips the bullet. See "Case" chapter in reference section.

Neck Size: To resize only the neck portion of a case.

Non-Corrosive: Usually refers to primers having a priming mixture which is free of corrosive compounds.

Ogive: Refers to the nose shape of a bullet. The radius of the curve of a bullet nose.

Powder: The propellent material used in most firearms. May be divided into two basic types: "Smokeless" powder and "Black" powder.

Pressure: The force exerted by a burning charge of powder in the chamber of a firearm. Expressed normally in pounds per square inch. See "Pressure" chapter in reference section.

Primer: A small metal cup containing the detonating mixture which is used to ignite the propellent powder. See "Primer" chapter in reference section.

Primer Pocket: The cavity in the base of a cartridge which receives and supports the primer.

Round: A military term meaning one single cartridge.

Round Nose: A bullet design which features a rounded nose.

SAAMI: Abbreviation for Small Arms and Ammunition Manufacturers Institute.

Seating Depth: The depth to which a bullet is seated below the case mouth.

Sectional Density: A bullet's weight, in pounds, divided by the square of its diameter in inches.

Swage: To form by forcing into or through a die.

Throat: That area of the bore immediately ahead of the chamber.

Trajectory: The path of a projectile in flight.

Velocity: The speed at which a projectile travels. Usually measured in feet per second at a given range.

Wad Cutter: A bullet design which features a sharp shoulder. Designed to cut a clean round hole in a paper target.

Web: That portion of a cartridge case between the bottom of the primer pocket and the interior of the case. See "Case" chapter in reference section.

Work-Harden: Brass becomes harder as it is worked. See "Case" chapter in reference section, also "Annealing".

X-Ring: Center of a target. Bulls-eye.

Yaw: The action of a projectile spinning erratically around its own axis. See "Accuracy with Jacketed Bullets" in reference section.

Zero: The range at which a firearm will hit the point of aim.

Catalog Section

While we have illustrated only a few of the many products which make up the Lyman line, we would like you to send for our complete 44 page catalog. Please fill out and mail the enclosed card for your free copy. All prices are subject to change without notice.

SPAR-T TURRET PRESS

This press combines both turret speed and C Frame strength. Its massive frame and 6 station turret, are ruggedly constructed of high-silicone, iron-steel castings. Positive stop, audible click action insures fool-proof alignment.

Spar-T Press only **$29.50**

Save with a Spar-T Set
contains:

- Spar-T Press
- Spar-T Primer Feed
- Spartan Primer Arm
- Spartan Ram
- Spartan Shell Holder
- Complete Die Set

Spar-T Set complete only **$49.95**

SPARTAN RELOADING PRESS

A truly rugged press at a sensational low price, this massive 11 lb. heavy-duty iron frame press will provide years of dependable service.

Spartan Press only **$13.50**

Save with a Spartan Set
contains:

- Spartan Press
- Spartan Ram
- Spartan Shell Holder
- Spartan Primer Arm
- Complete Die Set

Spartan Set complete only **$31.50**

Spartan Detachable Shell Holder Head

Precision cut and hardened to insure perfect case fit. Used with the Spartan Ram on either the Spartan or Spar-T Press.

Price **$2.50**

Spartan Ram

Designed for perfect alignment, convenience, economy. Fits Lyman Spartan or Spar-T Press.

Price **$3.50**

Spartan Universal Priming Arm

Seats all sizes and types of primers. No extras to buy. Fits Spartan or Spar-T Press.

Price **$3.00**

LYMAN-OHAUS D-5 SCALE (505 Grain Capacity)

Designed specifically for the reloader . . . . . this new Scale has a guaranteed sensitivity of one tenth of a grain. Its high capacity of up to 505 grains, permits the heaviest charges and even bullets to be weighed. Exclusive Lyman magnetic damping assures unsurpassed ease and speed, while genuine agate bearings provide dependable lifetime service.

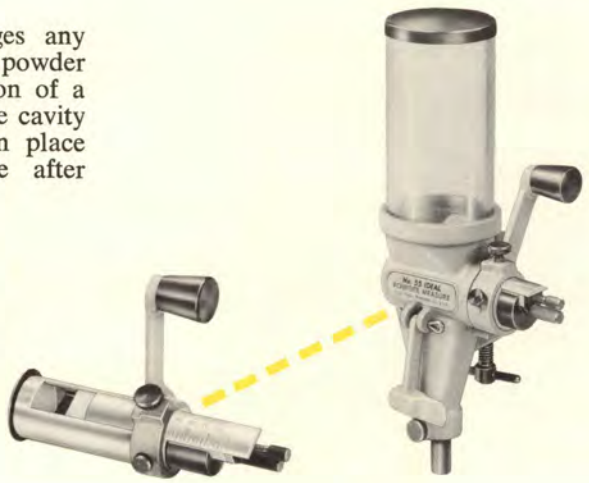
Price **$16.50**

The No. 55 POWDER MEASURE

This powder dispensing device charges any number of cases with black, or smokeless powder loads that are consistent within a fraction of a grain. Its three-slide micrometer adjustable cavity adjusts the load accurately and locks in place to provide accurate charging cartridge after cartridge.

Price **$17.50**

A unique three-slide adjustable cavity is the key to the 55's unfailing accuracy. Micrometer adjustments for both width and depth, minimizes cutting of course powder.



OUR CATALOG IS YOUR'S FOR THE ASKING. JUST FILL OUT AND MAIL THIS CARD. PLEASE DON'T FORGET TO LIST YOUR ZIP CODE.

ALL AMERICAN (TWO-DIE) RIFLE DIE SET

These sets are designed for bottleneck rifle cartridges using jacketed bullets. Each set consists of two dies; (1) full-length resizing and decapping die, (2) bullet seating and crimping die. Dies are carefully constructed of high grade "first quality" steel and polished to a mirror smooth interior finish.

Standard Two-Die Rifle Set (complete with wrench) ... **$11.50**

ALL AMERICAN (THREE-DIE) RIFLE DIE SET

These sets are designed for straight-taper rifle cases, and all other cartridges using cast bullets. They contain the same three dies as a pistol set.

Standard Three-Die Rifle Set (complete with wrench) **$13.50**

ALL AMERICAN (THREE-DIE) PISTOL DIE SET

Available for all pistol calibers this set can be used with either cast or jacketed bullets.

Each set consists of three dies; (1) Full-Length resizing and decapping die, (2) Separate (two-step) neck expanding die, (3) bullet seating and crimping die.

Standard Three Die Pistol Set (complete with wrench) **$13.50**

P-A RIFLE DIE

This bullet seating and crimping die is uniquely designed to give maximum alignment to bullets when seating them in bottleneck cases. The case neck and bullet are held in alignment throughout the seating process by a sliding inner sleeve.

Price **$6.50**

T-C PISTOL DIE

A lifetime of reloads, some 200,000 rounds can be pushed through this (tungsten carbide) full-length sizing and decapping die without a sign of wear. No lubrication required — cases come out with a polished, burnished, appearance. See Lyman catalog for caliber listing.

Price **$12.95**

SHELL CHAMFERING REAMER

Tapers case mouth for easier bullet starting. One size adapts to all cartridges.

Price **$3.00**

POWDER FUNNEL

This clear plastic powder funnel is designed to fill cases from 22 Hornet through 45-70 without inserts.

Price **$1.00**

Easy
SHOTSHELL RELOADER

You've never had it so easy, or so foolproof. The Easy straight-in-line station design eliminates all guesswork, all complicated adjustments—practically does your thinking for you.

A few simple strokes of the handle and POP — there's a perfectly finished reload, right in your hand, ready to shoot. Here, at last, is a high-production reloading tool with precision and capacity to satisfy the expert, yet with the simplicity and dependability of operation to suit the beginner. It comes to you completely assembled, adjusted and ready to go to work, complete with self aligning Crimp Starter. See Lyman catalog for specifics.
